NEW YORK, U. S. A.

TO  
THE YOUNG MOTHERS OF AMERICA,  
TOWARD THE SOLUTION OF WHOSE PROBLEMS  
THESE PAGES HAVE BEEN DEVOTED,  
THIS THIRD EDITION  
IS RESPECTFULLY DEDICATED  
BY THE AUTHOR.

## PREFACE TO THE THIRD EDITION

---

EIGHT years of constant use of the Catechism as a manual for nursery maids have shown the need of much fuller treatment of several subjects, notably that of infant feeding, than was given in the earlier editions. The same want has been expressed by mothers and nurses outside of institutions who have made the book a nursery guide.

The section upon Infant Feeding has, therefore, been almost entirely rewritten and much new material introduced, especially that relating to the selection and care of cow's milk, and its preparation and use in infant feeding. An effort has been made in the present volume to state more fully the principles underlying infant feeding, a knowledge of which is indispensable to the nurse or mother who would cope successfully with this difficult problem.

Much more space has been given in this edition to the nursing infant. Many other points relating to growth, training, toys, etc., have been touched upon

for the first time, so that the size of the book has been increased by nearly one half.

The author's aim has been not to alarm the mother by acquainting her with all the possible diseases and accidents which may befall her infant, but to open her eyes to matters which are her direct and chief concern.

It is, therefore, the needs of the well child, not the sick one, which have been considered. The well child must, in most cases, be left to the care of the mother or nurse for whose guidance and assistance these pages are intended. For directions in matters of illness, however, no mother or nurse should depend upon any manual, but upon the advice of a physician.

To Miss Marianna Wheeler, superintendent of the Babies' Hospital, whose long experience in training nurses has made her a most competent judge of their needs, I am indebted for many valuable suggestions.

It is believed that the mothers and nurses who have found the earlier editions of the Catechism helpful in the solution of some of their nursery problems will find even greater assistance from the present volume.

NEW YORK, *January, 1903.*

## PREFACE TO THE FIRST EDITION

---

WHEN in the fall of 1889 the Practical Training School for Nursery Maids was opened in connection with the Babies' Hospital of New York, the need was soon felt for some simple manual to put into the hands of the nurses. None could be found which fulfilled the requirements of simplicity, brevity, and exactness with reference to matters of infant feeding and nursery hygiene.

A series of questions was written out by the author for the purpose of formulating for the nurses under training those things which were matters of daily observation in the practical work of the Hospital. From time to time additions have been made to these, until the present size has been reached.

This Catechism is now, at the request of many friends, published, with the hope that it may serve a useful purpose in other institutions where similar schools for training may be established. At the same time, it is thought that it may be of value to many

mothers in the care of their own children, or a book which they may safely put into the hands of the ordinary (untrained) child's nurse.

In the preparation of this Catechism everything has been sacrificed to clearness and simplicity. It has been deemed best to emphasize strongly the essentials, without going into many minor details which would have increased materially the size of the book without adding to its usefulness. The style of question and answer has been adopted in order to impress more strongly the facts stated.

*March, 1894.*

## I

### THE CARE OF CHILDREN

#### BATHING

*At what age may a child be given a full tub bath?*

Usually when ten days old; it should not be given before the cord has come off.

*How should the bath be given?*

It should not be given sooner than one hour after feeding. The room should be warm; if possible there should be an open fire. The head and face should first be washed and dried; then the body should be soaped and the infant placed in the tub with its body well supported by the hand of the nurse. The bath should be given quickly, and the body dried rapidly with a soft towel, but with very little rubbing.

*At what temperature should the bath be given?*

For the first few weeks at 100° F.; later, during early infancy, at 98° F.; after six months,

at 95° F.; during the second year, from 85° to 90° F.

*Should a child be bathed whose body is covered with an eruption?*

Not as a rule, unless a physician has seen the case. Harm is often done in eczema and many other skin diseases by bathing with soap and water.

#### EYES

*How should the eyes of a little baby be cleansed?*

With a piece of soft linen and a lukewarm solution of salt or boric acid,—one fourth of an even teaspoonful to one pint of water.

*If pus appears in the eyes, what should be done?*

They should be cleansed every hour with a solution of boric acid (ten grains to one ounce of water). If the lids stick together, a little vaseline from a tube should be rubbed upon them at night. If the trouble is slight, this treatment will control it; if it is severe, a physician should be called immediately, as delay may result in loss of eyesight.

#### MOUTH

*How is an infant's mouth to be cleansed?*

An excellent method is by a swab made by twisting a bit of absorbent cotton upon a wooden tooth-

pick. With this the folds between the gums and lips and cheeks may be gently and carefully cleansed twice a day unless the mouth is sore. It is not necessary after every feeding. The finger of the nurse, often employed, is too large and liable to injure the delicate mucous membrane.

*What is sprue?*

It appears on the lips and inside the cheeks like little white threads or flakes. It is also called thrush. In bad cases it may cover the tongue and the whole of the inside of the mouth.

*How should a mouth be cleansed when there is sprue?*

It should be washed carefully after every feeding or nursing with a solution of borax or bicarbonate of soda (baking soda), one even teaspoonful to three ounces of water, and four times a day the boric-acid solution mentioned should be used.

---

SKIN

*How should the infant's skin be cared for to prevent chafing?*

First, not too much nor too strong soap should be used; secondly, careful rinsing of the body; thirdly, not too vigorous rubbing, either during or after the bath; fourthly, the very free use of dusting powder

in all the folds of the skin,—under the arms, behind the ears, about the neck, in the groin, etc. This is of the utmost importance in very fat infants.

*If the skin is very sensitive and chafing easily produced, what should be done?*

No soap should be used, but bran or salt baths given instead.

*How should a bran bath be prepared?*

One pint of wheat bran should be placed in a bag of coarse muslin or cheese-cloth, and this put in the bath water. It should then be squeezed for five minutes, until the water resembles a thin porridge.

*How should a salt bath be prepared?*

A teacupful of common salt or sea salt should be used to each two gallons of water.

*How should the buttocks be cared for?*

This is the most common place for chafing, as the parts are so frequently wet and soiled; hence the utmost pains should be taken that all napkins be removed as soon as they are wet or soiled, and the parts kept scrupulously clean.

*If the parts have become chafed, what should be done?*

Only bran and salt baths should be used, and in very severe cases even these may have to be omitted

for a day or two. The parts may be cleaned with sweet oil and a little absorbent cotton, and the skin kept covered with a dusting powder composed of starch two parts, boric acid one part.

*What is prickly heat, and how is it produced?*

It consists of fine red pimples, and is caused by excessive perspiration and the irritation of flannel underclothing.

*How should it be treated?*

Muslin or linen should be put next to the skin; the entire body should be sponged frequently with equal parts of vinegar and water, and plenty of the starch and boric-acid powder mentioned should be used.

#### CLOTHING

*What are the most essential things in the clothing of infants?*

That the chest shall be covered with soft flannel, the limbs well protected but not confined, and the abdomen supported by a broad flannel band, which should be snug but not too tight. It is important that the clothing should fit the body. If it is too tight it interferes with the free movements of the chest in breathing, and by pressing upon the stomach sometimes causes the infant to vomit soon after swal-

lowing its food. If the clothing is too loose it is soon thrown into deep folds or bunches, which cause much discomfort. No pins should be used, but, instead, all bands about the body should be basted. The petticoats should be supported by shoulder straps.

*How should the infant be held during dressing and undressing?*

Nothing is more awkward than to attempt to dress a young baby in a sitting posture. It should lie upon the nurse's lap until quite old enough to sit alone, the clothing being drawn over the child's feet, not slipped over the head.

*Of what use is the band?*

It protects the abdomen, but its most important use is to support the abdominal walls in very young infants, and in this way to prevent the occurrence of rupture.

*How long is this band required?*

The snug flannel band, not usually more than four months. In healthy infants this may then be replaced by the knitted band, which may be worn up to eighteen months. The band is an important article of dress in the case of thin infants whose abdominal organs are not sufficiently protected by fat.

With such, or with those prone to diarrhœa, it is often advisable to continue the band until the third year.

*What changes are to be made in the clothing of infants in the summer?*

Only the thinnest gauze flannel undershirts should be worn, and changes in temperature should be met by changes in the outer garments. The greatest care should be taken that children are not kept too hot in the middle of the day, while extra wraps should be used morning and evening, especially at the seashore or in the mountains.

*Should older children be allowed to go with their legs bare?*

If strong and well there is no objection to this in very hot weather. In cold weather, however, it is doubtful if any children are benefited by it, particularly in a changeable climate like that of New York. Many delicate children are certainly injured by such attempts at hardening.

*What sort of underclothing should be worn during cold weather?*

Never the heaviest weight, even in winter. Four grades are usually sold, the next to the heaviest being thick enough for any child.

*Do little children require as heavy flannels as older people?*

Not as a rule. They usually live in a warm nursery; their circulation is active; and they always perspire easily during their play. When they go out of doors, the addition of coats and leggings renders thick flannels unnecessary.

*Are not many little children clothed too thinly for the ordinary house?*

Very few. The almost invariable mistake made in city homes is that of excessive clothing and too warm rooms. These two things are among the most frequent reasons for their taking cold so easily.

#### NAPKINS

*How should napkins be taken care of?*

They should be immediately removed from the nursery when soiled or wet. Soiled napkins should be kept in a receptacle with a tight cover, and washed as soon as possible.

*Should napkins which have been only wet be used a second time without washing?*

It is no doubt better to use only fresh napkins, but there is no serious objection to using them twice unless there is chafing of the skin. Clean napkins,

changed as soon as wet or soiled, are of much importance in keeping the skin healthy.

*What are the important things to be observed in washing napkins?*

Soiled napkins should not be allowed to dry, but should receive a rough washing at once; they should then be kept in soak in plain water until a convenient time for washing,—every day or every other day,—when they should be washed in hot suds and boiled at least fifteen minutes. Afterward they should be very thoroughly rinsed or they may irritate the skin, and ironed without starch or blueing. They should never be used when damp.

#### NURSERY

*What are the essentials in a good nursery?*

As large a room as possible should be selected—one that is well ventilated, and always one in which the sun shines at some part of the day, as it should be remembered that an average child spends here at least three fourths of its time during the first year. The nursery should have dark shades at the windows, but no extra hangings or curtains; about the baby's crib nothing but what can be washed should be allowed. The air should be kept as fresh and as pure as possible. There should be no plumb-

ing, no drying of napkins or clothes, no cooking of food, and no gas burning at night. A small wax night-light answers every purpose.

*How should a nursery be heated?*

Best by an open fire; next to this by a Franklin stove. The ordinary hot-air furnace of cities has many objections, but it is not so bad as steam heat from a radiator in the room. A gas stove is even worse than this, and should never be used, except, perhaps, for a few minutes during the morning bath.

*At what temperature should a nursery be kept during the day?*

Best, 66° to 68° F., measured by a thermometer hanging three feet from the floor. Never should the temperature be allowed to go above 70° F.

*At what temperature during the night?*

During the first two or three months, not below 65° F. After three months the temperature may go as low as 55° F. After the first year it may be 50° or even 45° F.

*At what age may the window be left open at night?*

Usually after the third month, except when the outside temperature is below freezing point.

*How often should the nursery be aired?*

At least twice a day—in the morning after the child's bath, and again in the evening before the child is put to bed for the night. This should be done thoroughly, and the child should be removed meanwhile to another apartment. It is well to air the nursery whenever the child is out of the room.

*What symptoms are seen in a child who is kept in too hot a room?*

It becomes pale, loses appetite, shows symptoms of indigestion, occasionally vomits, stops gaining in weight, perspires very much, and takes cold easily because of this and also because of the great difference between the indoor and outdoor temperatures. Its condition may be such as to lead one to suspect very serious illness.

#### AIRING

*At what age may a child go out of doors in the fall and spring?*

Usually at one month. In the summer it may go out when one week old.

*When in winter?*

Airing in the room may be begun when the child is one month old, at first only fifteen or twenty minutes at a time. At three months it may go out on

pleasant days, being kept in the sun and out of the wind.

*What are the best hours for airing out of doors?*

In summer and early autumn a child may be out almost any time between seven in the morning and sunset; in winter and early spring, a young child only between 10 or 11 A. M. and 3 P. M., although this depends somewhat upon the climate. In New York and along the Atlantic coast the early mornings are apt to be damp and the afternoons raw and cloudy.

*On what kind of days should a baby not go out?*

In sharp winds, when the ground is covered with melting snow, and when it is extremely cold. A child under four months old should not usually go out if the thermometer is below freezing point; nor one under eight months old if it is below 20° F.

*What are the most important things to be attended to when the child is out in its carriage?*

To see that the wind never blows in its face, that its feet are properly covered and warm, and that the sun is never allowed to shine directly into its eyes when the child is either asleep or awake.

*Of what advantage to the child is going out?*

Fresh air is required to renew and purify the

blood, and this is just as necessary for health and growth as proper food.

*What are the effects produced in infants by fresh air?*

The appetite is improved, the digestion is better, the cheeks become red, and all signs of health are seen.

*Is there any advantage in having a child take its airing during the first five or six months in the nurse's arms?*

None whatever. A child can be made much more comfortable in a baby carriage, and can be equally well protected against exposure by blankets and the carriage umbrella.

*What are the objections to an infant's sleeping out of doors?*

There are no real objections. It is not true that infants take cold more easily when asleep than awake, while it is almost invariably the case that those who sleep out of doors are stronger children and less prone to take cold than others.

*What can be done for children who take cold upon the slightest provocation?*

They should be kept in cool rooms, especially when asleep. They should not wear such heavy

clothing that they are in a perspiration much of the time. Every morning the body, particularly the chest and back, should be sponged with cold water ( $50^{\circ}$  to  $60^{\circ}$  F.).

*How should this cold sponge bath be given?*

The child should stand in a tub containing a little warm water, and a large bath sponge filled with cold water should be squeezed two or three times over the body. This should be followed by a vigorous rubbing with a towel until the skin is quite red. This may be used at three years, and often at two years. For infants a little higher temperature ( $65^{\circ}$  to  $70^{\circ}$ ) may be used.

#### WEIGHT, GROWTH, AND DEVELOPMENT

*Of what importance is the weight of the child?*

Nothing else tells so accurately how well it is thriving.

During the first year a record of the weight is almost indispensable; throughout childhood it is of much interest and is the best guide to the physical condition. It will well repay any mother or nurse to keep such a record.

*How frequently should a child be weighed?*

Every week during the first six months, and at

least once in two weeks during the last six months of the first year. During the second year a child should be weighed at least once a month.

*How rapidly should an infant gain in weight during the first year?*

There is usually a loss during the first week of from four to eight ounces; after this a healthy child should gain from four to eight ounces a week up to about the sixth month. From six to twelve months the gain is less, usually from two to four ounces a week.

*Is it to be expected that bottle-fed infants will gain as rapidly as those who are nursed?*

They seldom do so during the first month; after that time under favourable circumstances the gain is usually quite as regular, and during the latter half of the first year it is likely to be more continuous than in a nursing infant, because the latter usually loses weight at the time of weaning.

*Why do they not gain so rapidly at first?*

It takes a few weeks for the stomach to become accustomed to cow's milk, and until this is accomplished it is necessary to make the milk very weak or the child's digestion will be upset.

*For a child of average weight at birth (seven to seven and a half pounds) what should be the weight at the different periods during the first year?*

At three months it should be twelve to thirteen pounds; at six months, fifteen to sixteen pounds; at nine months, seventeen to eighteen pounds; at one year, twenty to twenty-two pounds. At five months a healthy child will usually double its weight, and at twelve months it will usually treble its weight.

*Do all healthy infants gain steadily in weight during the first year?*

As a rule they do; yet it is seldom the case that one gains every week for the entire year. With most infants there are from time to time periods of a few weeks in which no gain is made. These are more often seen from the seventh to the tenth month and frequently occur when the child is cutting teeth, sometimes during very hot weather.

*Is it true that every infant who gains rapidly in weight is thriving normally?*

Not invariably. Some who are fed upon prepared infant foods increase rapidly in weight but not in strength, nor in their development in other respects.

*Is the weight of as much value in the second year as a guide to the child's condition?*

After the first year, the gain in weight is seldom continuous; there are many interruptions, some depend on season, and others often occur without apparent cause.

*At what age should the fontanel close?*

The average is about eighteen months. It seldom closes earlier than fourteen months, and should it remain open at two years something is wrong.

*At what age should a child hold up its head?*

As a rule during the fourth month, and often during the third month, the head can be held erect when the body is supported.

*When does an infant first laugh aloud?*

Usually from the third to the fifth month.

*When does it begin to reach for toys and handle them?*

Usually from the fifth to the seventh month.

*At what age should a child be able to sit and stand alone?*

At seven or eight months a healthy child is usu-

ally able to sit erect and support the body. During the ninth and tenth months are usually seen the first attempts to bear the weight upon the feet, and at eleven or twelve months most children can stand with assistance.

*When should a child walk alone?*

The first attempts are generally seen in the twelfth or thirteenth month. At fifteen or sixteen months the average child is able to run alone.

*What conditions postpone these events?*

Prematurity, a very delicate constitution, any severe or prolonged illness, and especially chronic disturbances of digestion making feeding difficult. A common cause of late sitting, standing, or walking is rickets.

*Should a child be urged to walk?*

Never; he is usually quite willing to do so as soon as his muscles and bones are strong enough. None of the contrivances for teaching children to walk are to be advised.

*When do children begin to talk?*

Generally at one year a child can say "papa" and "mamma" or other single words. At the end of the second year the average child is able to put words together in short sentences.

*If at two years the child makes no attempt to speak, what should be suspected?*

Either that the child is a deaf-mute or that it is mentally deficient, although this is occasionally seen in children who are only very backward.

*Table showing the Average Weight, Height, and Circumference of Head and Chest of Boys<sup>1</sup>*

At birth.....	Weight.....	7½ pounds.
	Height.....	20½ inches.
	Chest.....	13½ "
	Head.....	14 "
One year.....	Weight.....	20½ pounds.
	Height.....	29 inches.
	Chest.....	18 "
	Head.....	18 "
Two years .....	Weight.....	26½ pounds.
	Height.....	32½ inches.
	Chest.....	19 "
	Head.....	19 "

	Height . . . . .	48 inches.
	Chest . . . . .	24½ "
Nine years . . . . .	Weight . . . . .	60 pounds.
	Height . . . . .	50 inches.
	Chest . . . . .	25 "
Ten years . . . . .	Weight . . . . .	66½ pounds.
	Height . . . . .	52 inches.
	Chest . . . . .	26 "

#### DENTITION

*How many teeth are there in the first set?*

Twenty.

*What is the time of their appearance?*

The two central lower teeth are usually the first to appear, and come from the fifth to the ninth month; next are the four upper central teeth, which come from the eighth to the twelfth month. The other two lower central teeth and the four front double teeth come from the twelfth to the eighteenth month. Then follow the four canine teeth, the two

---

upper ones being known as the "eye teeth," and the two lower as the "stomach teeth"; they generally come between the eighteenth and the twenty-fourth month. The four back double teeth, which complete the first set, come between the twenty-fourth and thirtieth month.

At one year a child usually has six teeth.

At one and a half years, twelve teeth.

At two years, sixteen teeth.

At two and a half years, twenty teeth.

*What are the causes of variation?*

The appearance of teeth varies in different families; in some they come very early, in others much later. The teeth may come late as a result of prolonged illness and also from rickets.

*What symptoms are commonly seen with teething?*

In healthy children there is very often fretfulness and poor sleep for two or three nights; there may be loss of appetite, so that only one half the usual amount of food is taken; there is salivation or drooling, and often slight fever; there may be some symptoms of indigestion, such as vomiting or the appearance of undigested food in the stools. In delicate children all these symptoms may be much more severe.

*How long do these symptoms last?*

Usually only three or four days; but there may be no gain in weight for two or three weeks.

*What is the cause of most of the other symptoms attributed to teething?*

Nearly all of them come from indigestion due to bad feeding.

## II

### INFANT FEEDING

*What is the best infant food?*

Mother's milk.

*Of what is mother's milk composed?*

Thirteen parts solids and eighty-seven parts water.

*What are the solids?*

Fat, sugar, proteids, and salts.

*What is the fat?*

The cream.

*What is the sugar?*

It is lactose, or milk sugar.

*What are the proteids?*

The curd of the milk.

*Are all these elements necessary?*

Yes; we cannot expect to rear a healthy infant unless they are all in his food.

*Of what use is the fat?*

It is needed for the growth of the bones, the

nerves, the fat of the body, and the production of heat.

*Of what use is the sugar?*

It is needed for the production of heat, and to make fat in the body.

*Of what use are the proteids?*

They are needed for the growth of the cells of the body, such as those of the blood, the various organs, and the muscles.

*Of what use are the salts?*

Particularly for the growth of bone.

*Of what use is the water?*

By means of the water the food is kept in a state of minute subdivision or in solution, so that the delicate organs of a young infant can digest it. It is also necessary to enable the body to get rid of its waste.

#### NURSING

*Should all mothers attempt to nurse their children?*

As a rule they should do so, but there are many conditions when they should not.

*What are the most important ones?*

If the mother has or has had tuberculosis or any other serious chronic disease, or is herself in very delicate health, she should not try. She is likely soon

to fail in nourishing her child, and the attempt may do herself much harm as well as injure the child.

*How often should infants be nursed during the first two days of life?*

Usually only four or five times daily, since there is very little milk secreted at this time.

*When does the milk come in abundance?*

Usually on the third day, sometimes not until the fourth or fifth day.

*Should the infant be fed anything additional during the first two days?*

Usually not; if much food were necessary, we may be sure Nature would have provided it. Water may be given if the infant shows signs of thirst.

*How frequently should an infant be nursed during the first week?*

After the third day, every two hours during the day and twice during the night. The frequency during the rest of the first year is given in the following table:

PERIOD.	Nursings in 24 hours.	Interval by day.	Night nursings (10 P. M. to 6 A. M.)
1st and 2d day.....	4	6 hours.	1
3 days to 6 weeks ...	10	2 "	2
6 weeks to 3 months.	8	2½ "	2
3 to 5 months.....	7	3 "	1
5 to 12 months.....	6	3 "	0

*How long should the child be kept at the breast for one nursing?*

Not over twenty minutes.

*Should the child take both breasts at one nursing?*

If the milk is very abundant one breast may be sufficient, otherwise both breasts may be taken.

*What are the important things to be attended to in nursing?*

First, regularity; it is just as important as in the case of bottle-feeding. Secondly, the nipples should be kept clean by being washed after every nursing.

*What should be the diet of a nursing mother?*

She should have a simple but generous diet with plenty of fluids; three regular meals may be given, and gruel, milk, or cocoa at bed-time and sometimes between meals. She may take eggs, cereals, most soups, and nearly all vegetables, avoiding sour fruits, salads, pastry, and most desserts. Meat should not be taken more than twice daily, and in many cases but once. She should take but little tea or coffee, and ordinarily no wine or beer.

*Are fruits likely to disturb a nursing infant?*

Sour fruits in rare cases may do so, but sweet fruits and most cooked fruits are useful.

*What else is important in the life of the nursing mother?*

That she should have regular out-of-door exercise as soon after her confinement as her condition will permit; that she should be as free as possible from unnecessary cares and worry; that her rest at night should be as little disturbed as possible, and that her bowels move regularly every day.

*Do the emotions of the mother affect the milk?*

They have a very marked effect upon it; uncontrolled emotions such as grief, excitement, fright, passion, or excessive worry, or even extreme fatigue, may cause the milk to disagree with an infant or even make it acutely ill.

*Does menstruation affect the milk?*

In nearly all cases the quantity of milk is lessened so that the infant is not satisfied and may gain less in weight or not at all. In many cases the quality of the milk is also affected to such a degree as to cause slight disturbances of digestion, such as restlessness, colic, and perhaps some derangement of the bowels. In a few, attacks of acute indigestion are excited.

*Is regular menstruation a reason for stopping nursing?*

Not invariably; as a rule both functions do not

go on together. But if the child is gaining regularly in weight between the periods, nursing may be continued indefinitely, although it may be well to feed the infant wholly or in part during the first day or two that the mother is unwell.

*What symptoms indicate that a nursing infant is well nourished?*

The child has a good colour, sleeps for two or three hours after nursing, or, if awake, is quiet, good-natured, and apparently comfortable. It has normal movements of the bowels and gains steadily in weight.

*What are the symptoms which indicate that a child who is nursing is not properly nourished?*

It does not gain in weight, cries frequently, sleeps irregularly, is always uncomfortable, suffers from colic, and the movements contain undigested food. When the milk is scanty it will often nurse a long time at the breasts, sometimes three quarters of an hour, before stopping. At other times it may take the breast for a moment only, and then turn away in apparent disgust.

*What should be done when such symptoms appear?*

This depends upon the severity of the symptoms and how long they have lasted. If the child has

made no gain for three or four weeks, is constantly uncomfortable, and has symptoms of indigestion, nursing should be stopped entirely. If there is some gain in weight, nursing may be continued and the mother's manner of life altered with the hope of improving the milk. The bottle may be given once or twice in twenty-four hours, or at all the night feedings.

*Is there any objection to a baby being partly nursed and partly fed?*

None whatever; it is often better from the outset to feed the baby during the night, in order not to disturb the mother's rest.

*What changes should be made if a nursing infant habitually vomits?*

If this occurs soon after nursing, the infant has usually taken too much and the time of nursing should be shortened, or one breast may be given instead of two; the nursing should also be interrupted by occasional rests, so that the milk is not taken too fast.

If the vomiting occurs some time after nursing and is repeated, it is a sign of indigestion; often because the milk is too rich in fat. The intervals between nursings should then be lengthened; the breast milk may be diluted by giving one or two

tablespoonfuls of plain boiled water, lime-water, or barley-water, five or ten minutes before nursing; the mother should eat less hearty food, especially less meat.

*What should be done if the infant has frequent or habitual colic?*

This is usually because the milk is too rich in proteids; the mother should take more out-of-door exercise, eat less meat, and seek to control her emotions; all causes of worry should be removed.

*Can constipation in a nursing infant be controlled through the mother's milk?*

Only to a limited extent. It is important that the mother's bowels be regular and her digestion good. An increase in the meat and milk of her diet is sometimes beneficial.

#### WEANING

*At what age should the child be weaned from the breast?*

Usually weaning should be begun at nine or ten months by substituting one feeding a day for one nursing, later two feedings, and thus gradually the child is to be taken from the breast altogether.

*What is the principal reason for weaning earlier?*

The most important one is that the child is not thriving—not gaining in weight and not progressing

normally in its development. Serious illness of the mother, or pregnancy, may make weaning necessary.

*At what age should the weaning be completed?*

Generally at one year. In summer it may sometimes be advisable to nurse an infant a little longer rather than wean in warm weather; but even then the dangers of weaning are much less than those of continuing to nurse, as is so often done, after the milk has become very scanty and poor in quality.

*When should a child who is weaned from the breast be taught to drink from the cup, and when to take the bottle?*

If weaning is done as early as the eighth or ninth month it is better to give the bottle; if at the eleventh or twelfth month the infant should be taught to drink or be fed with a spoon.

*How may some of the difficulties in weaning be overcome?*

By feeding every nursing infant once a day or by giving it water regularly from a feeding-bottle. It then becomes accustomed to the bottle. This is a matter of great convenience during the whole period of nursing when the mother or nurse is from necessity away from the child for a few hours, and when more feeding is required at weaning time the child does not object.

*When should an infant be weaned from the bottle?*

This should be begun at the end of the first year; except at the night feeding the bottle should not be given after a child is fourteen months old.

*Is there any objection to an infant taking the bottle until two or three years old?*

There are no advantages and some serious objections. Older infants sometimes become so attached to the bottle that it is only with the greatest difficulty that they can be made to give it up. Many refuse milk altogether as soon as the bottle is taken away, and cannot be made to take milk during childhood except from a bottle. Such a "bottle habit" is troublesome, unnecessary, and should be prevented.

*Can a baby just weaned take cow's milk of the same proportions as one of the same age who has had cow's milk from birth?*

Very rarely; to give a baby who has had nothing but the breast from birth, plain cow's milk, or even that milk which a bottle-fed baby of the same age might take, is almost certain to cause indigestion. The change in the food is quite a marked one, and should be made gradually by beginning with a very weak milk and increasing its strength as the baby becomes accustomed to take cow's milk.

*What would be the proper proportions for an infant weaned at four or five months?*

About the same as for a healthy bottle-fed infant of two months; the quantity of course should be larger. The food can in most cases be gradually increased so that in two or three weeks the usual strength for the age can be taken.

*What would be the proper proportions for an infant weaned at nine or ten months?*

About the same as for a bottle-fed infant at four or five months, to be increased as indicated above.

*Will not a child lose in weight when placed upon so low a diet?*

Very often it will do so for the first week or two, but after that will gain quite regularly; the acute indigestion, however, which generally accompanies the use of stronger milk will, in most cases, cause a greater loss.

#### ARTIFICIAL FEEDING

*What foods contain all the elements present in mother's milk?*

The milk of other animals,—cow's milk being the only one which is available for use.

*Is it not possible for infants to thrive upon other foods than those containing fresh milk?*

They may do so for a time, but never perma-

nently. The long-continued use of other foods as the sole diet is attended with great risk.

*What are the dangers of such foods?*

Frequently scurvy is produced (see page 141), often rickets, and in other cases simply a condition of general malnutrition,—the child does not thrive, is pale, and its muscles soft and flabby.

#### THE SELECTION AND CARE OF MILK USED FOR INFANT FEEDING

*What are the essential points in milk selected for the feeding of infants?*

That it comes from healthy cows, and that it is clean and fresh.

*Is it not important to select a rich milk?*

By no means; in fact the very rich milk of highly bred Jerseys and Alderneys has not been found nearly so satisfactory in infant feeding as that from some other herds, such, for example, as the common “grade cows.”

*Which is the better, milk from one cow or the mixed milk of several cows?*

The mixed, or “herd milk,” is usually to be preferred, since it varies little from day to day; while that from a single cow may vary considerably.

*How fresh is it important that cow's milk should be for the best results in infant feeding?*

This depends very much upon the season, and how carefully milk is handled. As ordinarily handled at the dairy and in the home, milk should not be used for infants in winter after it is forty-eight hours old; in summer not after it is twenty-four hours old, and it may be unsafe in a much shorter time. When handled with especial care milk may be safe for a longer time.

*What are the two essentials in handling milk?*

1. That it be kept clean and free from contamination. This necessitates that cows, stables, and milkers be clean, and that transportation be in sealed bottles; also that those who handle the milk do not come in contact with any contagious disease. All milk-pails, bottles, cans, and other utensils with which the milk comes in contact should be sterilized shortly before they are used, by steam or boiling water.
2. That it be cooled immediately after leaving the cows, and kept at as low a temperature as possible; to be efficient this should not be above 50° F.

Milk produced under hygienic conditions and handled with special care is sold in bottles in a number of cities under the name of "certified," "guaranteed," or "inspected" milk. When available such

milk should be used for infants. Of course the extra care bestowed in its production and transportation increases the cost of the milk, but the best will usually be found in the end to be the cheapest.

*How should milk be handled in the home when obtained fresh from the cows?*

That to be used for infants should be strained through a thick layer of absorbent cotton or several thicknesses of cheese-cloth into quart glass jars or milk bottles which should be covered and cooled immediately, best by placing the bottles quite up to their necks in ice water or cold spring water, where they should stand for at least half an hour. That required for children who take plain milk may now be poured into half-pint bottles, stopped with cotton, and put in the ice-chest, or the coolest place possible. This first rapid cooling is very important and adds much to the keeping qualities of the milk. Milk loses its heat very quickly when cooled in water, but very slowly when it is simply placed in a cold room. After standing four or five hours the top-milk may be removed; after twelve to sixteen hours the cream may be removed.

*How should milk be handled when bottled milk is purchased?*

It should be cooled as just described, as its tem-

perature is usually somewhat raised during transportation. If it has been bottled at a dairy, the cream or the top-milk may be removed after an hour or so.

*How should milk and cream be handled when they are purchased in bulk?*

Such milk should never be used for infants when it is possible to obtain bottled milk, as it is much more liable to contamination. Both cream and milk should be poured at once into covered vessels and kept in the coolest place possible. The cream and top-milk will seldom rise upon such milk with any satisfactory regularity.

*What are the important things to be secured in nursery refrigerators?*

Absolute cleanliness is essential; hence the inner portion should be of metal. Those made entirely of metal are unsatisfactory as in them the ice melts very quickly. If the ordinary metal refrigerator sold is encased in a wooden box, we have the best form. Another easy way of securing the same result is to make for the refrigerator a covering or "cosey" of felt or heavy quilting, which can be easily removed when wet or soiled.

The compartments of the refrigerator should be so arranged that the bottles of milk are either in

contact with the ice or very near it. The supply of ice should be abundant. Often the amount of ice is so small, and the bottles so far away, that the temperature of the milk is never below 60° or 65° F. To be really effective a refrigerator should have a temperature where the milk is placed of not over 50° F. The temperature should be tested with the nursery thermometer from time to time to ascertain what results are being obtained. Spoiled milk owing to faulty refrigerators is to be blamed for many attacks of acute illness among infants. Next to the feeding-bottles it is the one thing in the nursery which should receive the closest attention.

#### THE MODIFICATION OF COW'S MILK

*Can cow's milk be fed to infants without any changes?*

No; for although it contains essentially the same elements as mother's milk, they are not in the same proportions.

*Is this a matter of much importance?*

It is of the greatest importance. There are few infants who can digest cow's milk unless it is changed. To change cow's milk so as to make it more nearly resemble mother's milk is called *modifying cow's milk*.

*How is this milk whose proportions have been changed distinguished from the original unchanged milk?*

The changed milk is usually called "modified milk"; the original unchanged milk is known as "plain milk," "whole milk," "straight milk," or is referred to simply as "milk."

*What are the principal differences between cow's milk and mother's milk?*

Cow's milk has a little more than half as much sugar; it has nearly three times as much proteids and salts; its proteids are much more difficult of digestion; its reaction is acid, that of mother's milk is alkaline.

*Are there any other important things to be considered?*

Yes; mother's milk is always fed fresh and is practically sterile. Cow's milk is generally kept twenty-four hours and sometimes much longer. It is always to a greater or less degree contaminated by dirt and germs, the number of which increases rapidly (1) with the age of the milk; (2) in proportion to amount of the dust or dirt which enters it; (3) with any increase in the temperature at which the milk is kept.

It is just as important for success in infant feed-

ing that these conditions receive attention as that the proportions of the different elements of the milk are right.

*How is the acidity of cow's milk overcome?*

By the addition of lime-water or bicarbonate of soda. If lime-water is used, one ounce to twenty ounces of food is generally required; if soda is used, twenty grains to twenty ounces of food.

*How is the sugar best increased?*

By adding milk sugar to the food; one ounce to each twenty ounces of food will give the proper quantity for the first four or five months. This will make the proportion about the same (between 6 and 7 per cent) as in mother's milk.

*How should the sugar be prepared?*

Simply dissolved in boiled water; if the solution is not clear, or if there is a deposit after standing, it should be filtered by pouring through a layer of absorbent cotton, half an inch thick, which is placed in an ordinary funnel.

*Will not cane (granulated) sugar answer as well?*

Not as a rule; however, there are many infants who get on very well when cane sugar is used. It has the advantage of being much cheaper. A good

grade of milk sugar is somewhat expensive, costing from twenty-five to sixty cents a pound, and cheap samples are apt to contain impurities.

*If cane sugar is used, what amount should be added?*

Considerably less than of the milk sugar. Usually about half the quantity (half an ounce to twenty ounces of food) is as much as most infants can digest. If the same quantity is used as of the milk sugar, the food is made unduly sweet, and the sugar is likely to ferment in the stomach and cause colic.

*Is not the purpose of the sugar to sweeten the food in order to make it palatable?*

Not at all; although it does that, its real use is to furnish one of the essential elements needed for the growth of the body, and the one that is required by young infants in the largest quantity.

*How do we know that this is so?*

By the fact that in good breast milk the amount of sugar is greater than that of the fat, proteids, and salts combined.

*We have seen that cow's milk has nearly three times as much proteids (curd) and salts as mother's milk. How are these to be diminished?*

By diluting the milk.

*Will it be sufficient to dilute the milk twice (i. e., add two parts of water to one part of milk)?*

Not for a very young infant. Although this will give about the quantity of proteids present in mother's milk, the proteids of cow's milk are so much more difficult for the infant to digest, that in the beginning it should be diluted five or six times for most infants.

*If cow's milk is properly diluted and lime-water and sugar added does it then resemble mother's milk?*

No; the mixture contains too little fat.

*What is the easiest way of overcoming this?*

By increasing the fat in the milk before dilution. It may be done by using top-milk or a mixture of milk and cream.

*What is top-milk?*

It is the upper layer of milk removed after standing a certain number of hours in a milk bottle, glass jar, or any tall vessel with straight sides. The strength of the top-milk is measured by the fat it contains—e. g., a 10-per-cent milk contains 10 per cent fat; 7-per-cent milk contains 7 per cent fat, etc. The amount of fat depends upon the proportion of the milk removed.

*How is 10-per-cent top-milk secured?*

By removing the upper third of the milk, or about ten ounces from a quart, after standing at least four hours.

*How is 7-per-cent top-milk secured?*

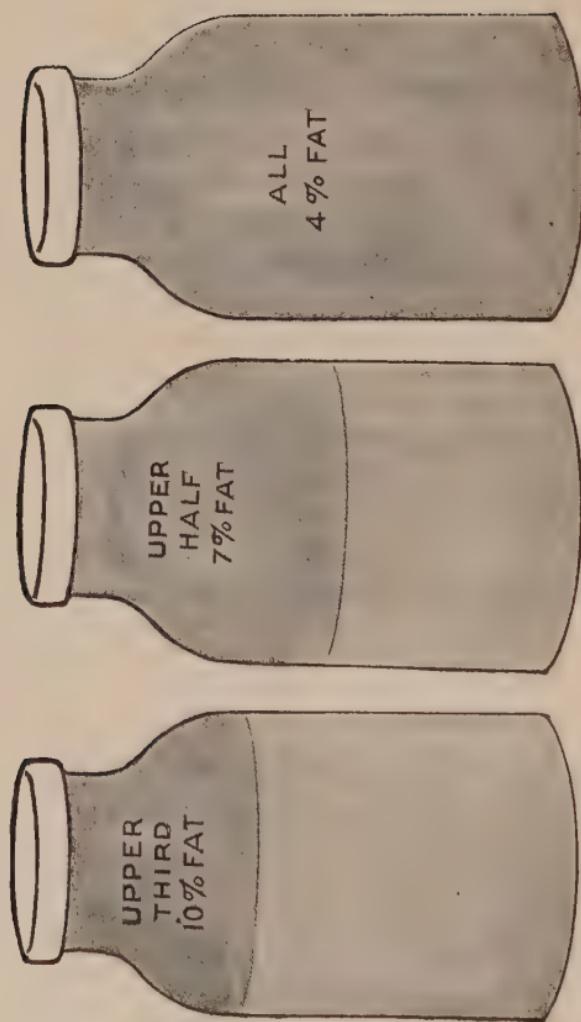

By removing the upper half or sixteen ounces from a quart.

The upper third and the upper half will give the percentage of fat mentioned with a good milk of average richness, which contains about 4 per cent fat. If rich Jersey milk is used, thirteen ounces should be removed from a quart to obtain the 10-per-cent milk, and twenty ounces to obtain the 7-per-cent milk. On the other hand if the milk used is poor in fat, not more than eight ounces can be removed having 10 per cent fat, and not more than thirteen ounces having 7 per cent fat.

*When and how should top-milk be removed?*

If milk fresh from the cows or before the cream has risen be put into bottles and rapidly cooled, the top-milk may be removed in as short a time as four hours. In the case of bottled milk it makes little difference if it stands a longer time, even until the next day.

This should not be poured off. It may be re-

The percentage of fat in different layers of milk.

moved by a spoon or a siphon, but the best method is by a small cream dipper<sup>1</sup> holding one ounce.

### *What is cream?*

Cream is often spoken of as if it were the fat in milk. It is really the part of the milk which contains most of the fat. It differs from milk chiefly in containing much more fat.

### *In what ways is cream now obtained?*

(1) By skimming, after the milk has stood usually for twenty-four hours; this is known as "gravity cream." (2) By an apparatus known as a separator; this is known as "centrifugal cream"; most of the cream now sold in cities is of this kind. The richness of any cream is indicated by the amount of fat it contains.

The usual gravity cream sold has from 16 to 20 per cent fat. The cream removed from the upper part (one fifth) of a bottle of milk has about 16 per cent fat. The usual centrifugal cream has 18 to 20 per cent fat. The heavy centrifugal cream has 35 to 40 per cent fat.

---

<sup>1</sup> Sold by James Dougherty, 409 West 59th Street, for 20 cents. In this also the milk sugar can be measured, 2 scant dipperfuls being equal to one ounce of sugar by weight. If the sugar is measured in a tablespoon, 2½ even tablespoonfuls may be calculated as one ounce.

## FOOD FOR THE EARLY MONTHS—FIRST PERIOD

*What relation should the proteids bear to the fat in the early months?*

They should be about one third the fat, the proportion usually present in mother's milk.

*Is this necessary throughout the first year?*

It is not; older infants can usually digest a larger proportion of proteids.

*How can the proper proportion of proteids and fat be most easily secured?*

By using for dilution a 10-per-cent milk (i. e., milk containing 10 per cent fat), which serves as the primary formula from which all the other formulas for this period are derived. In 10-per-cent milk the proteids are exactly one third the fat.

*How can we get the 10-per-cent milk?*

(1) As top-milk, using the upper third of an average milk after standing as described on page 55. (2) By mixing equal parts of plain milk and ordinary cream (containing about 16 per cent fat).

*Is it better to obtain the 10-per-cent milk by using a mixture of milk and cream, or as top-milk?*

If one can get milk fresh from the cows, the top-

milk is to be preferred on account of freshness. The food can then be made up when the milk is but a few hours old. In cities, if one uses bottled milk the upper third may also be used. But if one buys milk and cream separately, it is usually more convenient to mix these, as the cream will not rise upon milk a second time with any uniformity.

*How should milk be prepared for a baby during the early months?*

It is convenient to make up twenty ounces of food at a time. The first step is to obtain the 10-per-cent milk, of which, for the first two or three days, not more than two ounces should be used in twenty ounces of food; for the next few days, three ounces; then, for a few days, four ounces, etc. There will be needed also one ounce of lime-water and one ounce of milk sugar in each twenty ounces. The rest of the food will be boiled water.

These formulas written out would be as follows:

*First Series of Formulas—for the Early Months*

	I.	II.	III.	IV.	V.
10-per-cent milk ..	2 oz.	3 oz.	4 oz.	5 oz.	6 oz.
Milk sugar .....	1 "	1 "	1 "	1 "	1 "
Lime-water .....	1 "	1 "	1 "	1 "	1 "
Boiled water .....	17 "	16 "	15 "	14 "	13 "
	20 oz.				

As the milk sugar dissolves in the water the total in each column will be exactly twenty ounces. The food is strengthened by gradually increasing the milk and reducing the water.

The approximate composition of these formulas expressed in percentages is as follows:

FORMULA.	Fat.	Sugar.	Proteids.
I . . . . .	1.00	5.50	0.33
II . . . . .	1.50	6.00	0.50
III . . . . .	2.00	6.00	0.66
IV . . . . .	2.50	6.00	0.80
V . . . . .	3.00	6.50	1.00

*Why is it necessary to make the food so weak at first?*

Because the infant's stomach is not accustomed to take cow's milk; but if we begin with a very weak milk the stomach can be gradually trained to digest it. If we began with a strong milk the digestion might be seriously upset.

*How rapidly can the food be increased in strength from Formula I to II, from II to III, etc.?*

No absolute rule can be given. Usually we begin with I on the second day; II on the fourth day; III at one week or ten days; but after that make the increase more slowly. A large infant with a strong

digestion will bear a rather rapid increase and may be able to take V by the time it is three or four weeks old. A delicate child with a feeble digestion must go much slower and may not reach V before it is ten or twelve weeks old. It is important with both classes to increase the food gradually, always allowing at least three days between each change.

*What general rule can be given for increasing the food?*

To increase when the infant is not satisfied but is digesting well.

*In the series of formulas given in the table the quantities are mentioned for making only twenty ounces of food. How should it be prepared when more than this quantity is needed?*

It is equally convenient to make up 25 ounces, 30 ounces, 35 ounces, or 40 ounces at a time.

To make—

25 ounces of any formula add one quarter more of each ingredient.

30	"	"	"	"	one half	"	"	"
35	"	"	"	"	three quarters	"	"	"
40	"	"	"	"	twice as much	"	"	"

Thus 25 ounces of Formula I would be obtained by using  $2\frac{1}{2}$  ounces of milk,  $1\frac{1}{4}$  ounces of sugar and lime-water,  $21\frac{1}{4}$  ounces of water; 30 ounces of the same would require 3 ounces milk,  $1\frac{1}{2}$  ounces

lime-water and sugar, and  $25\frac{1}{2}$  ounces water; 35 ounces would require  $3\frac{1}{2}$  ounces milk,  $1\frac{3}{4}$  ounces lime-water and sugar, and  $29\frac{3}{4}$  ounces water. The amount of water need not be calculated in any case, but after measuring carefully the other ingredients enough water should be added to bring the total up to the amount required.

*Would not increasing the quantity sometimes be better than increasing the strength of the food?*

It is often better to increase the quantity. With most infants it is well in the early weeks to alternate, first increasing the quantity, then, if not satisfied, the strength of the food; the next time increasing the quantity again, etc.

*How great an increase in the quantity should be made at one time?*

One may make up five ounces additional food; but the first two days only three ounces of the additional amount should be given; the next two days, four ounces; after two days more, the five ounces may be given.

#### FOOD FOR THE MIDDLE MONTHS—SECOND PERIOD

*What is the second period of feeding?*

It usually begins at the end of the third or fourth

month and continues until the tenth or eleventh month.

*What changes may be made in the milk of a healthy infant in this period?*

A higher proportion of proteids may be given. Instead of being only one third the fat as in the first period, they may now be made one half the fat.

*How is this accomplished?*

By using for dilution instead of 10-per-cent milk, one in which the fat is only 7 per cent; for in this the proteids are exactly one half the fat.

*How is 7-per-cent milk obtained?*

(1) As top-milk, by taking the upper half after standing as described on page 55; or (2) by using one fourth ordinary cream, containing 16 per cent fat, and three fourths plain milk.

*How is the food prepared using the 7-per-cent milk?*

Very much like that with the 10-per-cent milk; twenty ounces are made up at one time, lime-water, milk sugar, and boiled water being added.

*What further additions may be made?*

In the latter part of the second period, farinaceous food (see page 70) may be added to the milk,

this taking the place of part of the water and part of the sugar.

*Second Series of Formulas—Middle Months*

	I.	II.	III.	IV.	V.
7-per-cent milk . . . . .	7 oz.	8 oz.	9 oz.	10 oz.	11 oz.
Milk sugar . . . . .	1 "	1 "	1 "	1 "	1 "
Lime-water . . . . .	1 "	1 "	1 "	1 "	1 "
Boiled water . . . . .	12 "	11 "	10 "	5 "	3 "
Barley gruel . . . . .	0 "	0 "	0 "	4 "	5 "
	20 oz.				

Since the sugar dissolves, the total will be twenty ounces in each column.

Of any of the formulas, 25 ounces is made by using one quarter more of each ingredient; 30 ounces, by using one half more; 35 ounces, by using three quarters more; 40 ounces, by using twice as much, exactly as described in the First Series on page 61.

The approximate composition of these formulas expressed in percentages is as follows:

FORMULA.	Fat.	Sugar.	Proteids.
I . . . . .	2.50	6.50	1.25
II . . . . .	2.80	6.50	1.40
III . . . . .	3.15	7.00	1.55
IV . . . . .	3.50	6.00	1.75
V . . . . .	4.00	6.50	2.00

*How should the food be increased during this period?*

Beginning with I of this Series, which should usually follow V of the First Series (page 59), the increase may generally be made in a week or ten days to II; in about two weeks more to III; now more slowly to IV and V. When IV or V have been reached, the same formula may sometimes be continued for three or four months with no other change than an increase in the quantity.

#### FOOD FROM TEN TO FIFTEEN MONTHS—THIRD PERIOD

*What changes may be made in the food when the infant has reached the age of ten or eleven months?*

The proteids may be still further increased, and the sugar and the lime-water reduced until plain milk is given.

*How may this best be done?*

At first one feeding a day of plain milk and barley gruel may be given; later, two feedings; then three feedings, etc. Let us suppose an infant to be taking such a modified milk as Formula IV or V (page 64), six feedings a day. The plain milk diluted only with barley gruel would at first replace one of these feedings; then two, three, four, etc., these changes being made at intervals of about two weeks.

The proportions of the milk and barley gruel should at first be about  $5\frac{1}{2}$  ounces milk,  $2\frac{1}{2}$  ounces barley; later, 6 ounces milk, 3 ounces barley; still later, 7 ounces milk, 2 ounces barley, until finally plain milk is given to drink and the cereals given separately with a spoon. This is reached with most infants at fourteen or fifteen months; with many at twelve or thirteen months. Other forms of farinaceous food may of course be used in the place of the barley, and in the same proportions.

With some infants the addition of a pinch of bicarbonate of soda may be advantageously made to each milk-feeding when the lime-water is omitted, but with most this is unnecessary.

If the infant strongly objects to the taste of the milk when the milk sugar has been omitted, a small quantity (one fourth to one half teaspoonful) of granulated sugar may for a time be added to each feeding, then gradually reduced.

#### GENERAL RULES FOR GUIDANCE IN THE USE OF THE FORMULAS GIVEN

1. These formulas are not intended for sick children nor for those suffering from any marked symptoms of indigestion. For such infants special rules are given later.

2. One should always begin with weak proportions; this especially applies to (1) infants fed from birth; (2) those just weaned, whose food should be much weaker than the age and weight would seem to indicate; (3) infants whose power of digestion is unknown. If the first formula tried is weaker than the child can digest, the food can be strengthened every two days until it is found what the child is able to do. If the mistake is made of making the food too strong at first, an attack of indigestion will probably follow.

3. The gradual increase in the strength of the food is just as important as to make it weak in the beginning. It is seldom wise to advance more rapidly than from one formula to the next one in any of the series given. Abruptly increasing the strength of the food is likely to upset the digestion.

4. The signs indicating that the food should be increased are, that the infant is not satisfied, not gaining in weight, but is digesting well. One should not increase the food, however, so long as the child seems perfectly satisfied and is gaining six to eight ounces a week, even though both the quantity and the strength of the food are considerably below the average.

5. After the food has been strengthened, there is sometimes seen a slight discomfort for a day or two;

but unless such symptoms are severe or steadily increase, one should not go back to the weaker formula; for in most cases the infant soon becomes accustomed to the stronger food and quite able to digest it.

6. In the early weeks it is well first to increase the strength of the food, the next time the quantity, then the strength again, etc. After the fourth or fifth month, the quantity, chiefly, should be increased.

7. In the early weeks an increase may be necessary every few days; in the later months sometimes the same formula may be continued for two or three months.

8. One should not be disturbed in the first two or three weeks, if the gain in weight is slight or even if there is none. If the infant does not lose weight, if it is perfectly comfortable, sleeps most of the time, and does not suffer from any symptoms of indigestion, such as colic, vomiting, etc., one may be sure that all is going well and that the infant is becoming used to its food. With the demands of the child's appetite the food may be increased every few days, and soon the gain in weight will come and will then be continuous.

9. If the child is perfectly comfortable one should not be disturbed at the small and somewhat

---

constipated movements from the bowels which are apt to occur while the food is very weak. If the bowels move of themselves once a day one should be content. As the food is gradually strengthened, this symptom soon passes off; while, if an injection or medicine is used to produce freer movements, the functions of the bowels are soon disturbed.

10. While the increase of the food should always be slow and gradual, its reduction, when any marked symptoms of indigestion arise, should be immediate and considerable. For a moderate disturbance, one or two ounces of food may be removed from each bottle just before it is given, and this replaced by the same quantity of boiled water. If the disturbance is severe, the food should be diluted at least one half, and at the same time the quantity much reduced.

11. After the food has been reduced on account of any form of disturbance of digestion, one should be careful not to go back too rapidly to the original formula; a second attack of indigestion will always occur from a slighter cause than the first one. It is surprising how long a time is required, often several weeks, for young infants to recover entirely from an attack of acute indigestion, even though it was not very severe.

## THE ADDITION OF OTHER FOODS TO MILK

*How long should modified milk be continued without the addition of other food?*

This depends upon circumstances; usually, for about six months; but if the infant is thriving satisfactorily the milk may be used alone for ten or eleven months; with some infants who have especial difficulty in digesting cow's milk, it is often advisable to begin the use of other food at three or four months.

*What is the first thing to be used with milk?*

Farinaceous food in some form, usually as a gruel.

*How are these gruels made?*

They may be made directly from the grains or from some of the prepared flours (page 114). The flours are usually to be preferred as being more simple of preparation.

*How should they be used in making the food?*

They should be cooked separately, rather than with the milk; when the food is mixed, they take the place of a portion of the water in any of the formulas given on pages 59 and 64.

*How much of the gruel should be used?*

If it is prepared as recommended on page 113, it may make according to circumstances from one sixth to one half the total quantity of food.

*Which of the farinaceous foods are to be preferred?*

Those most used are barley, oatmeal, arrowroot, and farina. There is not much difference in their nutritive value; oatmeal gruel is somewhat more laxative.

*What value do these substances possess as infant foods?*

Some of the starch is digested and absorbed; but their chief value is believed to be that when added to milk they render the curd more easily digested by preventing it from coagulating in the stomach in large tough masses. This is certainly true with some infants, but there are others who are not at all benefited, and not a few young infants whose digestion is made distinctly worse by the addition of farinaceous food, particularly when employed in considerable quantity. Its use for all infants is not to be recommended.

*What further additions may be made to the diet of healthy infants during the first year?*

Beef juice, the white of egg, and orange juice.

*How and when may beef juice be used?*

With infants who are strong and thriving satisfactorily it may be begun at ten or eleven months; two teaspoonfuls may be given daily, diluted with the same quantity of water, fifteen minutes before the mid-day feeding; in two weeks the quantity may be doubled; and in four weeks six teaspoonfuls may be given. The maximum quantity at one year should not be more than two or three tablespoonfuls.

With delicate infants who are pale and anæmic, beef juice is more important, and it may often be wisely begun at five or six months in half the quantities mentioned.

*When should white of egg be used?*

Under the same conditions as beef juice, particularly with infants who have difficulty in digesting the proteids (curd) of milk. At six months half the white of one egg may be given at one time, and soon after this the entire white of one egg. The best manner of cooking is the "coddled" egg (see page 115).

*When should orange juice be begun?*

Usually about the eleventh or twelfth month; it should be given about one hour before the feeding; two teaspoonfuls at first, then one tablespoonful at a time, and later three or four tablespoonfuls. It

---

is particularly useful when there is constipation. It should always be strained, and care should be taken that it is sweet and fresh.

#### OVERFEEDING

*What is meant by overfeeding?*

Giving an infant too much food; either too much at one time or too frequently. Overfeeding is sometimes practised during the day, but is chiefly done at night.

*Is not an infant's natural desire for food a proper guide as to the quantity given?*

The appetite of a perfectly normal infant usually is; but overeating is a habit gradually acquired and may continue until twice as much food as is proper is taken in the twenty-four hours. This habit is most frequently seen in infants whose digestion is not quite normal; because of the temporary relief from discomfort experienced by taking food into the stomach, they often appear to be hungry the greater part of the time, especially at night.

*What harm results from overfeeding?*

All food taken in excess of the needs of the body becomes a burden to the child. It lies in the stomach or bowels undigested, ferments, and causes wind

and colic; when this is longer continued, serious disturbances of digestion are soon produced. The infant is restless, fretful, constantly uncomfortable, sleeps badly, and stops gaining and may even lose in weight. Such symptoms may lead to the mistaken conclusion that too little food is given, and it is accordingly increased, when it should be diminished. One of the results of long continued overfeeding is dilatation or stretching of the stomach.

*What should guide one as to the quantity of food to be given to any infant?*

(1) The size of the infant's stomach at the different months; (2) the amount of milk which the healthy nursing infant gets; (3) the quantities with which most children do best. The table of quantities and intervals of feeding, on page 87, gives the average figures derived from these sources. It will seldom be wise to go beyond the limits there stated.

#### THE CHANGES IN THE FOOD REQUIRED BY SPECIAL SYMPTOMS OR CONDITIONS

*Why is it that an infant so often vomits some of its food within a few moments after finishing its bottle?*

Usually because the quantity is too large. Sometimes it is due to the fact that the food is taken too

rapidly, from too large a hole in the nipple. It may be due to too tight clothing, or to moving the child about in such a way as to press upon the stomach.

*What are the principal causes of, and the changes in the food required by habitual vomiting, regurgitation, or spitting up of small quantities of food between feedings, sometimes repeated many times a day?*

This is always a symptom of gastric indigestion. In such conditions the fat and often the sugar also should be reduced. The fat may be reduced by using, in the first series of formulas for the early months (see page 59), 7-per-cent milk instead of 10-per-cent milk; or, if the symptoms are very severe, plain milk may be substituted in the same formulas.

Reduction in the sugar may be made by adding only one half ounce of milk sugar to each twenty ounces of the food; in severe cases the sugar may be omitted altogether.

In addition to these changes it is often advisable in the vomiting cases to double the amount of lime-water—i. e., use two ounces to each twenty ounces of food.

The malted foods and all other foods containing much sugar usually aggravate the symptoms.

The intervals between meals should generally be half an hour longer, and sometimes an hour longer, than when digestion is normal.

*What are the causes of, and food changes required by a constant and excessive formation of gas in the stomach, leading to distention and pain, or eructations (belching) of gas and often of a sour, watery fluid?*

This is often associated with habitual vomiting, but it depends chiefly upon the sugar, which should be greatly reduced or omitted entirely.

*What changes should be made when there is habitual colic?*

This is generally due to an accumulation of gas in the intestines which forms there because the proteids (curd) of the milk are not digested. They should be reduced by using in the early months a weaker formula—i. e., instead of Formula V of the First Series, IV might be used, or, for a short time, even III. The proteids may be reduced in the middle period by using weaker formulas. If we desire to reduce the proteids without reducing the fat, we may use for the First Series, only cream; for the Second Series, the 10-per-cent milk.

Another means of relieving habitual colic is the use of peptonized milk (page 94); the dilution with

barley-water instead of plain water is sometimes useful.

*What change should be made if curds appear in the stools regularly or frequently?*

This is usually associated with habitual colic, and has to be managed exactly like that condition, by the means just described.

*How should the milk be modified for chronic constipation?*

The constipation of the first weeks of life has been already referred to (page 69); it usually disappears as the food is gradually strengthened in all its proportions. Habitual constipation at a later period is difficult to overcome by diet alone. It sometimes depends upon the fact that the proteids are too high, and sometimes that the fat is too low. Hence it is more frequent when infants are fed upon plain milk diluted once or twice, than when 7-per-cent or 10-per-cent milk is used, and diluted to a greater degree. In general, constipation calls for more cream and less milk. In some cases the use, in place of milk sugar, of ordinary brown sugar, in half the quantity, is of assistance; or of some of the malted foods (Mellin's food, malted milk, cereal milk) also in the place of milk sugar. In infants over nine months old, orange juice may be tried.

*What special modifications are required by very hot weather?*

During the warm season it is well to make the proportion of fat less than during cold weather. During short periods of excessive heat it should be much less. This is done by using 7-per-cent milk in place of 10-per-cent, in the First Series of formulas (page 59), or plain milk in place of the 7-per-cent milk in the Second Series (page 64). At such times also the usual food should be diluted, and water should be given freely between the feedings.

*What changes should be made in the food of a child who, with all the signs of good digestion, gains very little or not at all in weight?*

The quantity of food should be increased; but if the child will not (readily) take any more in quantity the strength should be increased by the use of the next higher formula.

*What changes are required for infants who habitually sleep badly?*

This is a very complicated condition, and may be due to indigestion resulting from too much food, or to hunger produced by too little food, or simply to frequent feeding at night. Each one of these requires special treatment.

*What changes in the food are required by slight indisposition?*

For slight general disturbances such as dentition, colds, sore throats, etc., it is usually sufficient simply to dilute the food. If this is but for two or three feedings, it is most easily done by replacing with boiled water an ounce or two of the food removed from the bottle just before it is given; if for several days, a weaker formula should be used.

*What changes should be made for a serious acute illness?*

For such attacks as those of pneumonia, bronchitis, measles, etc., attended with fever, the food should be diluted and the fat reduced as described on page 78. It should be given at regular intervals, rather less frequently than in health. Water should be given freely between the feedings. Food should not be forced in the early days of an acute illness, since the loss of appetite usually means an inability to digest much food.

*What immediate changes should be made in the food when the child is taken with an acute attack of gastric indigestion with repeated vomiting, fever, pain, etc.?*

All milk should be stopped immediately, and only boiled water given for ten or twelve hours;

afterward barley-water or whey may be tried, but no milk for at least twenty-four hours after the vomiting has ceased. When beginning the modified milk the quantity should be small and the fat low, which may be secured by the use of plain milk in either the First or Second Series of formulas, in the place of 10-per-cent or 7-per-cent milk. The proportion of lime-water may be doubled.

*What changes should be made for an attack of intestinal indigestion attended by looseness of the bowels?*

If this is not severe (only two or three passages daily) the fat should be lowered in the manner stated just above, and the milk should be boiled for five minutes. If curds are present in the stools, it may be still further diluted.

If the diarrhoeal attack is more severe, and attended by fever and foul-smelling movements of greater frequency, all milk should be stopped immediately, and the diet mentioned just above under the head of acute disturbances of the stomach should be employed.

*What changes in the food should be made when the child seems to have very little appetite and yet is not ill?*

The number of feedings should be reduced, the

interval being lengthened by one hour or even more. No greater mistake can be made than to offer food every hour or two to an infant who is not hungry. Such a course only prolongs and aggravates the disturbance.

*What other conditions besides the food greatly influence the child's digestion?*

Proper clothing, warm feet, regular habits, fresh air, clean bottles, and food given at the proper temperature, are all quite as important as the preparation of the food.

#### PREPARATION OF COW'S MILK AT HOME

*What articles are required for the preparation of cow's milk at home?*

Feeding-bottles, rubber nipples, an eight-ounce graduated measuring glass, a glass or agate funnel, bottle brush, cotton, alcohol lamp or, better, a Bunsen gas burner, a tall quart cup for warming bottles of milk, a pitcher for mixing the food, a wide-mouth bottle for boric acid and one for bicarbonate of soda, and a pasteurizer. Later, a double boiler for cooking cereals will be needed.

*What bottles are to be preferred?*

A cylindrical graduated bottle with a rather wide

neck, so as to admit of easy washing, and one which contains no angles or corners. A single size holding eight ounces is quite sufficient for use during the first year. All complicated bottles are bad, being difficult to clean. One should have as many bottles in use as the child takes meals a day.

*How should bottles be cared for?*

As soon as they are emptied they should be rinsed with cold water and allowed to stand filled with water to which a little bicarbonate of soda has been added. Before the milk is put into them they should be thoroughly washed with a bottle brush and hot soap-suds and then placed for twenty minutes in boiling water.

*What sort of nipples should be used?*

Only simple straight nipples which slip over the neck of the bottle. Those with a rubber or glass tube are too complicated and very difficult to keep clean. Nipples made of black rubber are to be preferred. The hole in the nipple should not be so large that the milk will run in a stream, but just large enough for it to drop rapidly when the bottle with the nipple attached is inverted.

*How should nipples be cared for?*

New nipples should be boiled for five minutes;

but it is unnecessary to repeat this every day as they soon become so soft as to be almost useless. After using, nipples should be carefully rinsed in cold water and kept in a covered glass containing a solution of borax or boric acid. At least once a day they should be turned wrong side out and thoroughly washed with soap and water.

*What sort of cotton should be used?*

The refined non-absorbent cotton is rather better for stoppering bottles, but the ordinary absorbent cotton will answer every purpose.

*Which is better, the Bunsen burner or the alcohol lamp?*

If there is gas in the house, the Bunsen burner is greatly to be preferred, being cheaper, simpler, and much safer than the alcohol lamp. If the lamp is used, it should stand upon a table covered with a plate of zinc or tin, or upon a large tin tray. The French pattern of alcohol lamp is the best.

*Give the directions for preparing the food according to any of the above formulas.*

The nurse's hands, bottles, tables, and all utensils should be scrupulously clean. First dissolve the milk sugar in boiling water, filtering if necessary. Then add the milk and cream and lime-water, mix-

ing the whole in a pitcher. A sufficient quantity of food for twenty-four hours is always to be prepared at one time. This is then divided into the number of feedings required for the day, each feeding being put in a separate bottle, and the bottle stoppered with cotton. The bottles should then be cooled rapidly by standing, first in tepid then in cold water, and afterward placed in an ice chest. If the milk is to be pasteurized or sterilized, this should precede the cooling.

#### DIRECTIONS FOR FEEDING INFANTS

*How should the bottle be prepared at feeding time?*

It should be taken from the ice chest, and warmed by standing in warm water which is deep enough to cover the milk in the bottle; it should then be thoroughly shaken and the nipple adjusted; the nurse should see that the hole in the nipple is not too large nor too small.

*How may the temperature of the milk be tested?*

Never by putting the nipple in the nurse's mouth. Before adjusting the nipple, a teaspoonful may be poured from the bottle and tasted, or a few drops may be poured through the nipple upon the inner surface of the wrist, where it should feel

quite warm but never hot; or a thermometer may be placed in the water in which the bottle stands. A dairy thermometer should be used, and the temperature of the water should be between 98° and 105° F.

*What is a simple contrivance for keeping the milk warm during feeding?*

A small flannel bag with a draw string may be slipped over the bottle.

*In what position should an infant take its bottle?*

For the first two or three months it is better, except at night, when it may be undesirable to take the infant from its crib, that it be held on the nurse's arm during the feeding; later it may lie on its side in the crib provided the bottle is held by the nurse until it has been emptied; otherwise a young infant readily falls into the bad habit of alternately sucking and sleeping, and often will be an hour or more over its bottle.

*How much time should be allowed for one feeding?*

Never more than twenty minutes. The bottle should then be taken away and not given until the next feeding time. Under no circumstances should

an infant form the habit of sleeping with the nipple in its mouth. A sleepy infant should be kept awake by gentle shaking until the food is taken, or the bottle should be removed altogether.

*Should an infant be played with soon after feeding?*

On no account; such a thing frequently causes vomiting and sometimes indigestion. After every feeding the infant should be allowed to lie quietly in its crib, and disturbed as little as possible.

#### INTERVALS OF FEEDING

*How often should a baby be fed during the first month?*

Every two hours during the day and twice during the night, or ten feedings during the twenty-four hours.

*At what age may the interval be made two and a half hours?*

Usually at five weeks.

*When may it be increased to three hours?*

Usually at two and a half months.

*Why should not a child be fed more frequently?*

It takes the stomach nearly two hours to digest a

meal at two months, and about two and a half hours at five or six months, and if the meals are too near together the second one is given before the first has been digested and vomiting and indigestion result. The meals should be far enough apart to give the stomach a little time for rest just before each feeding.

*Schedule for feeding Healthy Infants during the First Year*

AGE.	Interval between meals, by day.	Night feedings (10 P. M. to 7 A. M.).	No. of feedings in 24 hours.	Quantity for one feeding.	Quantity for 24 hours.
	Hours.			Ounces.	Ounces.
2d to 7th day.....	2	2	10	1 - $1\frac{1}{2}$	10-15
2d and 3d weeks.....	2	2	10	1 $\frac{1}{2}$ -3	15-30
4th and 5th weeks....	2	1	10	2 $\frac{1}{2}$ -3 $\frac{1}{2}$	25-35
6th week to 3d month.	2 $\frac{1}{2}$	1	8	3 - 5	24-40
3d to 5th month.....	3	1	7	4 - 6	28-42
5th to 9th month.....	3	0	6	5 - 7 $\frac{1}{2}$	30-45
9th to 12th month.....	4	0	5	7 - 9	35-45

This schedule gives the averages for healthy children. The smaller quantities are those required by small children whose digestion is not very vigorous. The larger quantities are those required by large children with strong digestion; in very few cases will it be advisable to go above these figures.

The interval is reckoned from the beginning of one feeding to the beginning of the next one.

*When should the interval between the feedings be lengthened?*

When there is gastric indigestion as shown by habitual vomiting or the regurgitation of food long after the bottle is finished; also when the appetite is very poor so that the infant regularly leaves some of its food.

*When should the interval between the feedings be shortened?*

This is done much too frequently; it is rarely advisable to feed any infant except one seriously ill, oftener than the time put down in the schedule.

#### REGULARITY IN FEEDING

*How can a baby be taught to be regular in its habits of eating and sleeping?*

By always feeding at regular intervals and putting to sleep at exactly the same time every day and evening.

*When should regular training be begun?*

During the first week of life.

*Should a baby be wakened to be nursed or fed if sleeping quietly?*

Yes, for a few days. This will not be required long, for with regular feeding an infant

---

soon wakes regularly for its meal, almost upon the minute.

*Should regularity in feeding be kept up at night as well as during the day?*

Only up to nine or ten o'clock; after that time a baby should be allowed to sleep as long as it will.

*At what age may a well baby go without food from 10 p. m. to 6 or 7 a. m.?*

Usually at four months, and always at five or six months. Night feeding is one of the most frequent causes of wakefulness and disturbed sleep.

#### STERILIZED MILK

*What is meant by sterilizing milk?*

Heating milk for the purpose of destroying germs.

*Does all cows' milk contain germs?*

Yes; even when handled most carefully, milk contains many germs; but when carelessly handled, and in summer, the number is enormous. While most of these are harmless or cause only the souring of milk, others are occasionally present which may produce serious diseases such as typhoid fever, diphtheria, scarlet fever, cholera, tuberculosis, and many forms of diarrhoea.

*Under what circumstances is it necessary to sterilize milk?*

1. In warm weather when it cannot be obtained fresh; hence always in cities during the summer.
2. When one cannot be certain that the cows are healthy, or that the milk has been carefully handled.
3. When the milk is to be kept for any considerable time (i. e., over twenty-four hours), especially if no ice can be had.
4. During epidemics of typhoid fever, scarlet fever, diphtheria, or any form of diarrhoeal disease.

*What are the two methods of heating milk?*

The first is known as *sterilizing*, where the milk is heated to 212° F. for one hour or one hour and a half; the second is known as *pasteurizing*, where the milk is heated to 155° or 170° F. for thirty minutes. A temperature of 155° F. continued for thirty minutes is sufficient to kill the germs of the diseases above referred to.

*Will milk which has been thus treated keep indefinitely?*

No; for although all the living germs may be killed, there are many undeveloped germs, or spores, which are not destroyed, and which soon grow into living germs. Milk heated to 212° F. for an hour

---

will keep upon ice for two or three weeks; that heated to 155° F. for two or three days.

*Is milk which has been sterilized always a safe food?*

No; for the reason that the milk may be so old, so dirty, and so contaminated before sterilizing that it may be still unfit for food, though it contains no living germs.

*Is cow's milk rendered more digestible by being heated in this way?*

Sterilizing milk does not improve the digestibility of milk but rather the contrary. Sterilized milk should be modified for infant feeding in the same way as milk which has not been heated.

*Is milk in any way injured by heating to 212° F. for an hour?*

There is abundant evidence that milk is rendered less digestible by such heating; also that it is more constipating, and that, for some children its nutritive properties are interfered with, so that it may cause scurvy; this, however, is not seen unless it is continued as the sole food for a long period. These objections are of so much importance that this plan of heating milk is not to be recommended for general use.

*When is it advantageous to heat milk to 212° F.?*

For use upon long journeys, such as crossing the ocean. Milk should then be heated for one hour upon two successive days, without removing the cotton stoppers from the bottles.

*Is milk in any way injured by heating to 155° F. for thirty minutes?*

This point is not yet definitely settled. Such heating does not affect the taste of milk and does render it more constipating. The unfavourable effects, if there are any, are so slight that they need not deter one from the use of pasteurized milk, even for long periods. The preference, however, should always be given to milk which is so clean and so fresh as not to require any heating.

*How should milk be pasteurized?*

A convenient form of apparatus is that known as Freeman's pasteurizer;<sup>1</sup> another is the Walker-Gordon pasteurizer.<sup>2</sup>

*How should milk be cooled after pasteurizing?*

Always by placing the bottles in cold water, so

---

<sup>1</sup> This can be obtained at 411 West Fifty-ninth Street, New York, with full directions; a tin one, at a cost of \$3, and a copper one, which is much more durable, for \$6.

<sup>2</sup> Obtained from any of the Walker-Gordon milk laboratories.

as to cool them rapidly; never by letting them stand at the temperature of the room, or by placing them, when warm, in an ice box.

*Why is this precaution necessary?*

Cooling in the air or in an ice box requires from two to four hours, and during that time a great many of the undeveloped germs may mature and greatly injure the keeping properties of the milk. In the cold water, milk can be cooled in from ten to twenty minutes if the water is frequently changed, or if ice is added to the water.

#### MODIFIED MILK OF THE MILK LABORATORIES

*What is "modified milk" of the milk laboratories?*

It is milk containing definite proportions of the fat, sugar, proteids, etc., put up usually according to the prescription of a physician, who indicates how much of the different elements he desires. The most reliable are the laboratories of the Walker-Gordon Company, which has branches in many of the large cities of the United States.

This is an excellent method of having milk prepared, since it can be done with greater care and cleanliness than are possible in most homes. It is besides a great convenience if circumstances

make it impossible to prepare the milk properly at home.

The laboratory should be used for infant feeding only by one who is somewhat familiar with this method of ordering milk.

#### PEPTONIZED MILK

*What is peptonized milk?*

Milk in which the proteids (curd) have been partially digested.

*How is this accomplished?*

By the action of a peptonizing powder which is composed of a digestive agent known as the extractum pancreatis and bicarbonate of soda, which is added to the plain or diluted milk. This is sold in tubes or in tablets, and it is the active ingredient of the peptogenie milk powder.

*Describe the process.*

The plain or modified milk is placed in a clean glass jar or bottle, and the peptonizing powder, which is first rubbed up with a tablespoonful of the milk, is added and the bottle shaken. The bottle is then placed in a large pitcher or basin containing water kept at the temperature of about 110° F., or as warm as the hand can bear comfortably, and left for

---

ten to twenty minutes if the milk is to be partially peptonized; for two hours if it is to be completely peptonized.

*What taste has partially peptonized milk?*

None, if it is continued for only ten minutes, but at the end of twenty minutes it begins to be bitter, when the process of digestion has gone further.

*How is the bitter taste avoided in partially peptonized milk?*

At the end of ten or fifteen minutes the milk may be placed in a saucepan and quickly raised to boiling point; this kills the ferment, so that the milk will not become bitter when warmed a second time. Or, the milk may be rapidly cooled by placing the bottles first in cool and then in ice water; in this way the ferment is not destroyed, and the milk may become bitter when warmed for feeding.

*Should the whole day's supply be peptonized at once, or each bottle separately just before the feeding?*

Either plan may be followed. If the former, it is better to raise the milk to boiling point after peptonizing; if the latter, it should not be peptonized more than ten minutes, for it will continue to peptonize while it is being taken by the child.

*Is not the bitter taste of completely peptonized milk a great obstacle to its use?*

Not in the case of young infants; one under four or five months old will usually take it without any objection after two or three feedings; but it cannot often be used for those who are much older.

*How much of the peptonizing powder should be used?*

There are required for one pint of plain milk, five grains of the extractum pancreatis and fifteen grains of bicarbonate of soda. This quantity is usually put up in a single tube or tablet. In the formulas previously given, less than this will be required; for the weaker formulas, one half or one third of the powder mentioned will be sufficient for one pint of food. For a single feeding of four ounces, one may use one eighth of a tube with a weak formula, or one sixth of a tube with a stronger formula.

*What are the advantages of peptonized milk?*

Partially peptonized milk is useful for young infants who have great difficulty in digesting the curd of milk, sometimes even when diluted as already described; completely peptonized milk, during acute attacks of indigestion.

*For how long a period may the use of peptonized milk be continued?*

Completely peptonized milk may be used for a few days, or at most a few weeks; partially peptonized milk may be used for two or three months, but not indefinitely; it should be left off gradually by shortening the time of peptonizing, and lessening the amount of the powder used.

## FEEDING DURING THE SECOND YEAR

*How many meals are required during the second year, and what are the most convenient hours?*

It is usually better to continue five meals throughout the second year, the hours being 6.30 and 10 A. M. and 2, 6, and 10 P. M. Some children will sleep from 6 P. M to 6 A. M. without waking, but unless there is a feeding at 10 P. M. children are apt to wake very early in the morning.

*Should each feeding be prepared at the time it is given, or all feedings at one time, as during the first year?*

During the second and third years it is better to prepare the milk for the entire day at one time. If it is to be modified by adding cream, water, etc., it is done exactly as during the first year.

Later, when only plain milk is used, the quantities needed for the different feedings should be put into one or into two bottles, which then may be pasteurized or not as may be necessary. In this way the different feedings are kept separate, and the day's supply of milk is not disturbed every time the child is fed, as otherwise is unavoidable. The food should be prepared as soon as possible after the daily milk supply is delivered in the morning.

*Give a proper diet for an average child from the twelfth to the fifteenth month.*

First meal: A bottle containing ten ounces, composed of milk, seven ounces, and three ounces of wheat, oatmeal, or barley gruel. If the milk is not up to the average in richness, one ounce of cream and six ounces of milk may be used. A pinch of salt and half a teaspoonful of granulated sugar may be added.

Second meal: Same as the first.

Third meal: Beef juice, one or two ounces, three times a week; an egg (coddled or soft boiled) twice a week; chicken or mutton broth, four to six ounces twice a week; and a bottle containing half the amount given at the first meal. A small thin piece of crisp toast may be given with the broth.

---

Fourth meal: Same as the first.

Fifth meal: Same as the first.

*What fruit may be given at this period?*

Only fruit juices, of which orange juice is the best; next to this the juice of fresh ripe peaches, apricots, or strawberries. All these should be strained very carefully through muslin to make sure that the child gets none of the pulp or seeds, both of which may cause serious disturbance. Of the orange or peach juice, from one to four tablespoonfuls may be allowed at one time; of the others about half the quantity. The fruit juice is best given one hour before the second feeding.

*When should the bottle as a method of feeding be given up?*

Most children can and should be taught to take their food from the cup or spoon by the time they are thirteen or fourteen months old. The bottle may be allowed at the night feeding for a few months longer, but its use during the day should not be permitted after the age mentioned (see page 44).

*Give a proper diet for an average child from the fifteenth to the twentieth month.*

First meal: Ten to twelve ounces of plain milk, warmed, taken from a cup.

Second meal: Two tablespoonfuls of oatmeal, hominy, wheaten grits, or some other cereal, thoroughly cooked from three to four hours and strained, with one or two ounces of thin cream, half a teaspoonful of sugar and salt; plain milk, from six to eight ounces.

Third meal: Besides the articles allowed for this feeding at fifteen months there may be given boiled rice (cooked three hours), usually with beef juice; stale bread, zwieback, or the Huntley and Palmer breakfast biscuits; if the molar teeth are through, rare scraped meat, such as beefsteak or mutton-chop, at first only a teaspoonful at a time; prune pulp, one or two tablespoonfuls; plain milk, from four to six ounces.

Fourth meal: Farina and milk, from ten to twelve ounces in all, alternating with arrowroot or granum and milk, or stale bread and milk.

Fifth meal: From ten to twelve ounces of plain milk from a bottle.

Orange juice and other fruit juices may be given as during the early part of the second year, and in somewhat larger quantity.

*Cannot most children take plain milk before they are fifteen months old?*

Many can but many cannot, or at least they do

much better when the milk is modified by the addition of cream and water or diluted with gruels.

*Give a proper diet for an average child from the twentieth to the twenty-fourth month.*

First meal: Plain milk, from ten to twelve ounces.

Second meal: The same cereals as during the preceding four months, except that they need no longer be strained, but they should still be very thoroughly cooked; plain milk, from six to eight ounces; piece of stale bread.

Third meal: Rare meat pulp (steak, chop, or roast beef), from one teaspoonful to one tablespoonful, well salted, and four ounces of chicken or mutton broth; on alternate days from two to four ounces of beef juice, or a soft egg mixed with bread crumbs or with one tablespoonful of well-cooked rice jelly; stale bread, without butter; and fruit; only water to drink.

Fourth meal: Farina, granum, barley, and milk, from ten to twelve ounces in all.

Fifth meal: From ten to twelve ounces plain milk.

*What fruits may be given at this period?*

If the child has a feeble digestion, only the fruit juices previously allowed; strong children may

have in addition prune pulp, baked apple, and apple-sauce. The prune pulp is prepared by stewing the dried prunes without sugar until they are very soft, and removing all the skin by putting the fruit through a strainer; of this from one to two tablespoonfuls may be given at one time. The baked apple should be given plain, and the apple-sauce should have very little sugar.

*How and when should water be given?*

Throughout the second year water should be given freely between the feedings, especially in warm weather; from one to three ounces may be given at one time, either from a spoon, a glass, or a bottle. The water should be boiled daily and then cooled. It should not be allowed to stand in the room, but fresh water should be put into the bottle each time.

## THE FEEDING OF OLDER CHILDREN

*How many meals are required during the third year?*

Usually but four, the 10 p. m. feeding being omitted when the child is two years old; otherwise the hours may be about the same as during the second year.

*Give a proper diet for an average child during the third year.*

Three quarters of an hour before breakfast the juice of an orange.

First meal: Two tablespoonfuls of a well-cooked cereal with cream, a little sugar, and salt; stale or dried bread and butter; glass of warm milk; soft egg three times a week.

Second meal: Glass of warm milk, or a cup of chicken or mutton broth, with a slice of stale or dried bread, a piece of unsweetened zwieback, or a Huntley and Palmer breakfast biscuit.

Third meal: Broth (when not given at second meal); meat—steak, chop, roast beef, roast lamb—or white meat of chicken, all scraped or very finely cut; potato, baked or boiled and mashed, or rice, or macaroni stewed very soft with milk; asparagus, or fresh peas, or string beans, or spinach, or stewed celery, all thoroughly cooked and mashed; bread and butter; junket, or plain custard twice a week; on other days prunes or baked apple or applesauce.

Fourth meal: From ten to fourteen ounces of warm milk, with bread, farina, arrowroot, barley, corn starch, or granum, and milk, or milk toast.

ARTICLES ALLOWED FROM THE THIRD TO THE  
SEVENTH YEAR

*Milk.*—This should be the basis of the diet; most children require about one quart daily. This usually needs no modification, but if the curd is somewhat difficult of digestion, it may be prepared by adding to six ounces of milk, one ounce of cream, and three ounces of water. The milk should be given warm.

*Cream.*—This is of great value, especially when there is a tendency to constipation. From two to four ounces may be given daily; but it is essential that it be fresh. It may be used upon cereals, upon potato, in broths, and mixed with milk. In many cases it is advisable to withhold milk and give only cream. Cream should be omitted if its use is followed by coating of the tongue, foul breath, looseness of the bowels, or other signs of indigestion.

*Eggs.*—They should be fresh, soft-boiled, poached, or coddled, but never fried. Some children tire readily of eggs, even though the manner of cooking is varied. Others will take an egg twice a day for an indefinite period with relish and benefit.

*Meats.*—Some form of meat should be given once a day. The best forms are beefsteak, mutton-chop,

and roast beef or lamb; next to these the white meat of chicken, or fresh fish, which should be boiled or broiled. Beef and mutton should be given rare.

*Vegetables.*—Potato may be given once a day, preferably baked, with the addition of cream or beef juice rather than butter. Of the green vegetables the best are asparagus tops, spinach, stewed celery, small carrots, string beans, fresh peas, and squash. Young beets may be used if thoroughly cooked. One of these vegetables should be given daily, always well cooked and mashed.

*Cereals.*—Nearly all these may be used, oatmeal, wheaten grits, hominy, rice, farina, and arrowroot. The most important part of the preparation is thorough cooking. If the grains are used, cereals should be cooked at least three hours, after having been previously soaked several hours; if the prepared (steamed) oats or wheat, they should be cooked at least one hour and a half; the prepared flours, at least twenty minutes. They should always be well salted, and given with milk or cream, but with little or no sugar.

*Broths and Soups.*—The meat broths are preferable to the vegetable broths. Nearly all varieties may be given. Plain broths are not very nutritious, but when thickened with arrowroot or cornstarch,

and when cream or milk is added, they are very palatable, and at the same time a valuable addition to the diet. Beef juice may be used as directed for the second year.

*Bread and Crackers.*—In some form these may be given with nearly every meal, with very little butter until the third year, as for young children cream is usually a better form of fat. All varieties of bread may be allowed when stale; also dried bread, zwieback, and oatmeal, Graham, or gluten crackers, or Huntley and Palmer breakfast biscuits.

*Desserts.*—The only ones that should be allowed up to the sixth year are junket, plain custard, rice pudding without raisins, and, not oftener than once a week, ice-cream. Of the last three, the quantity given should be very moderate.

*Fruits.*—They are an important part of a child's diet, and should be given in some form every day. Oranges, baked apple, and stewed prunes are the most to be depended upon. Raw apples in most cases should not be given. Peaches, pears, and grapes (with seeds removed) may be given when thoroughly ripe and fresh, but only in moderate quantity. Special care should be exercised in the use of fruits in very hot weather, and in cities where they may not always be fresh. Berries and cherries

are best deferred until children are five or six years old, and even then should be given very sparingly.

#### ARTICLES FORBIDDEN

The following articles of food are improper for a healthy child under four years of age in all circumstances. Nearly all of them should be prohibited in the case of children under seven years:

*Meats.*—Ham, sausage, pork in all forms, salt fish, corned beef, dried beef, goose, duck, game, kidney, liver and bacon, meat stews, and dressings from roasted meats.

*Vegetables.*—Those especially objectionable are cucumbers, radishes, green corn, and raw tomatoes. Nearly as bad are cabbage, cauliflower, and raw celery or onions. Stewed or fried potatoes, egg plant, and cooked tomatoes are not to be recommended.

*Bread and Cake.*—All hot bread, biscuits, or rolls; buckwheat and all other griddle cakes; all sweet cakes, particularly those containing dried fruits and those heavily frosted.

*Desserts.*—All nuts, candies, dried fruits; all canned or preserved fruits; pies, tarts, and pastry of every description.

*Drinks.*—Tea, coffee, wine, beer, soda-water, and cider.

*Fruits.*—Bananas; all fruits out of season; all stale fruits, particularly in cities and during the summer. Grapes are objectionable only on account of the seeds. With most of the other fruits it is the excess in quantity which makes them injurious.

#### GENERAL RULES TO BE OBSERVED IN FEEDING

Learning to eat proper things in a proper way forms a large part of a child's early education. If careful training in these matters is begun at the outset and continued, the results will well repay the time and effort required. A child who has been trained to eat properly can usually be trained to do anything else that is important.

Whether the child feeds himself or is fed by the nurse, the following rules should be observed:

1. Food at regular hours only; nothing between meals.
2. Plenty of time should be taken. On no account should the child bolt his food.
3. The child must be taught to chew his food. Yet no matter how much pains are taken in this respect, mastication is very imperfectly done by all children; hence up to the seventh year at least, all

meats should be very finely cut, all vegetables mashed to a pulp, and all grains cooked very soft.

4. Children should not be continually urged to eat if they are disinclined to do so at their regular hours of feeding, or if the appetite is habitually poor, and under no circumstances should a child be forced to eat.

5. Indigestible food should never be given to tempt the appetite when the ordinary simple food is refused; food should not be allowed between meals because it is refused at meal-time.

6. One serious objection to allowing young children highly seasoned food, entrées, jellies, pastry, sweets, etc., even in such small amounts as not to upset the digestion, is that children thus indulged soon lose appetite for the simple food which previously was taken with relish.

7. If there is any important article of a simple diet such as milk, meat, cereals, or vegetables, which a child habitually refuses, this should always be given first at the meal and other food withheld until it is disposed of. Children so readily form habits of eating only certain things and refusing others that such an inclination should be checked early.

8. If an infant refuses its food altogether, or takes less than usual, the food should be examined

to see if this is right. Then the mouth should be inspected to see if it is sore. If neither of these things is the cause, the food should be taken away and not offered again until the next feeding time comes.

9. In any acute illness the amount of food should be much reduced and the food made more dilute than usual. If there is fever, no solid food should be given. If the child is already upon a milk diet, this should be diluted, and in some cases partially peptonized.

10. In very hot weather the same rules hold, to give less food, particularly less solid food, and more water.

## FOOD FORMULAS

*Beef Juice.*—One pound of rare round steak, cut thick, slightly broiled, and the juice pressed out by a lemon-squeezer, or, better, a meat-press. From two to four ounces of juice can generally be obtained. This, seasoned with salt, may be given cold, or warmed by placing the cup which holds it in warm water. It should not be heated sufficiently to coagulate the albumin which is in solution, and which then appears as flakes of meat floating in the fluid.

*Beef Juice by the Cold Process.*—One pound of finely chopped round steak, six ounces of cold water, a pinch of salt; place in a covered jar and stand on ice or in a cold place, five or six hours or overnight. It is well to shake occasionally. This is now strained and all the juice squeezed out by placing the meat in coarse muslin and twisting it very hard. It is then seasoned and fed like the above.

Beef juice so made is not quite as palatable as that prepared from broiled steak, but it is even more nutritious, and is more economical, as fully twice as much juice can be obtained from a given quantity of meat. Beef juice prepared in either of these ways is greatly to be preferred to the beef extracts sold.

*Mutton Broth.*—One pound of finely chopped lean mutton, including some of the bone, one pint cold water, pinch of salt. Cook for three hours over a slow fire down to half a pint, adding water if necessary; strain through muslin, and when cold carefully remove the fat, adding more salt if required. It may be fed warm, or cold in the form of a jelly.

A very nutritious and delicious broth is made by thickening this with cornstarch or arrowroot, cooking for ten minutes and then adding three ounces of milk, or one ounce and a half of thin cream, to a half pint of broth.

*Chicken, Veal, and Beef Broths.*—These are made and used in precisely the same manner as mutton broth.

*Meat Pulp.*—A rare piece of round or sirloin steak, the outer part having been cut away, is scraped or shredded with a knife; one teaspoonful to one tablespoonful may be given, well salted, to a child of eighteen months. Scraping is much better than cutting the meat fine.

For this on a large scale, as in institutions, a Hamburg-steak cutter may be employed.

*Junket, or Curds and Whey.*—One pint of fresh cow's milk, warmed; pinch of salt; a teaspoonful of granulated sugar; add two teaspoonfuls of Fairchild's essence of pepsin, or liquid rennet, or one junket tablet dissolved in water; stir for a moment, and then allow it to stand at the temperature of the room for twenty minutes, or until firmly coagulated; place in the ice box until thoroughly cold. For older children this may be seasoned with grated nutmeg.

*Whey.*—The coagulated milk prepared as above is broken up with a fork and the whey strained off through muslin. It is best given cold. If some stimulant is desired, sherry wine in the proportion of one part to twelve, or brandy one part to twenty-

---

four, may be added. Whey is useful in many cases of acute indigestion.

*Barley Jelly from the Grains.*—Three tablespoonfuls of pearl barley; soak overnight, then place this in one quart of fresh water; add pinch of salt, and cook in double boiler steadily for four hours down to one pint, adding water from time to time; strain through muslin. When cold this makes a rather thick jelly. If a thinner gruel (barley water) is desired, one half the quantity of barley should be used.

*Oat, Wheat, or Rice Jelly.*—These are prepared from oatmeal, wheaten grits, and rice grains in the same manner as the barley jelly.

*Barley Jelly from the Flour.*—Either Robinson's patent barley or prepared barley flour of the Health Food Company may be used. One rounded tablespoonful of the flour, thoroughly blended with a little cold water, is added, stirring, to one pint of boiling water containing a pinch of salt; cook for twenty minutes in a double boiler, and strain. This makes a jelly of about the consistency of that made from the grains as above. It is essentially the same in composition, and much less trouble to prepare. A thinner gruel (barley water) is made by using half the quantity of flour.

When this is to be mixed with milk, it is well to add the milk to the barley gruel before removing from the fire, and stir two or three minutes, or until the milk has nearly reached the boiling point, when it should be removed and bottled.

*Oat or Wheat Jelly from the Flour.*—These are made from the prepared oat flour of the Health Food Company or Hubbell's prepared wheat flour. They are used like the barley.

*Imperial Granum.*—This is prepared and used in precisely the same way as the barley flour above mentioned, the gruel being mixed with milk before it is removed from the fire.

*Albumin Water.*—The white of one fresh egg; half a pint of cold water; pinch of salt; teaspoonful of brandy. This should be shaken thoroughly and fed cold either with a spoon or from a bottle. It is useful in cases of vomiting, and can sometimes be retained by a very irritable stomach.

*Lime-water.*—One heaping teaspoonful of slaked lime; one quart boiled or distilled water; place in a corked bottle and shake thoroughly two or three times during the first hour. The lime should then be allowed to settle, and after twenty-four hours the upper clear fluid carefully poured or siphoned off for use.

*Dried Bread.*—Either stale or fresh bread may be used; it is cut in thin slices and placed in the oven, with the door open, and quickly dried until it is crisp, but not browned. It is in many respects preferable to crackers for little children.

*Coddled Egg.*—A fresh egg, shell on, is placed in boiling water which is immediately after removed from the fire. The egg then cooks slowly in the water, which gradually cools, for seven or eight minutes, when the white should be about the consistency of jelly. For a delicate digestion the white only should be given, with salt; it can be easily separated from the yolk.

### III

## MISCELLANEOUS

#### THE BOWELS

*How many movements daily should an infant have during the first few weeks of life?*

Usually two or three a day for the first week, and then one or two each day.

*How many after a child is a month old?*

A healthy child should have at least one movement each day; many have two and some more than two; but it is the character of the stools rather than their number which is to be taken as the evidence of perfect digestion.

*What is the appearance of a healthy movement of a child who is taking nothing but milk?*

It is soft, yellow, and smooth, containing no lumps.

*When are the stools dark brown or black?*

While taking bismuth, iron, and sometimes when taking much meat or beef juice; also while taking

many of the prepared foods. They may be dark brown or black from blood. This last is a condition which may indicate serious illness.

*How may a child be trained to be regular in the action of its bowels?*

By endeavouring to have them move at exactly the same time every day.

*At what age may an infant be trained in this way?*

Usually by the second month if training is begun early.

*What is the best method of training?*

A small chamber, about the size of a pint bowl, is placed between the nurse's knees, and upon this the infant is held, its back being against the nurse's chest and its body firmly supported. This should be done twice a day, after the morning and afternoon feedings, and always at the same hour. At first there may be necessary some local irritation, like that produced by tickling the anus or introducing just inside the rectum a small cone of oiled paper or a piece of soap, as a suggestion of the purpose for which the baby is placed upon the chamber; but in a surprisingly short time the position is all that is required. With most infants, after a few weeks the bowels will move as soon as the infant is placed on the chamber.

*What advantage has such training?*

It forms the habit of having the bowels move regularly at the same hour, which is a matter of great importance in infancy and makes regularity in childhood much easier. It also saves the nurse much trouble and labour.

#### SLEEP

*Should a child sleep in the same bed with its mother or nurse?*

Under no circumstances, if this can possibly be avoided. Very young infants have often been smothered by their mothers, by overlying during sleep. If the infant sleeps with the mother, there is always the temptation to frequent nursing at night, which is injurious to both mother and child. Older children also should, if possible, have separate beds; many contagious diseases and bad habits are contracted by children sleeping together.

*How should an infant's bed be prepared?*

The mattress should be firm but soft, the pillow very thin, and the covering not excessive. A baby should not be allowed to sleep always in the same position, but should be changed from side to side. Hair pillows are useful in summer and for children who perspire very much.

---

*How much sleep is natural for a newly born baby?*

A baby with a good digestion and proper food will usually sleep at this period about nine tenths of the time.

*How much should a baby sleep at six months?*

About two thirds of the time.

*Up to what age should an older child take a nap during the day?*

Always until four years old, and if possible longer.

*At what age may an infant go all night without feeding?*

At five months a child should not be fed or nursed between 10 p. m. and 6 a. m. At two years a child can easily go from 6 p. m. to 6 a. m. without feeding.

*How should a baby be put to sleep?*

The room should be darkened and quiet, the child's hunger satisfied, and the child made generally comfortable and laid in its crib while awake.

*Is rocking necessary?*

By no means. It is a habit easily acquired, but hard to break, and a very useless and sometimes in-

jurious one. The same may be said of sucking a rubber nipple, or "pacifier," and all other devices for putting children to sleep.

*What are the principal causes of disturbed sleep?*

As quiet peaceful sleep is a sign of perfect health, disorders of sleep may be produced by almost anything which is wrong with the child.

1. Habitual disturbance of sleep in infants is most frequently associated with the food or feeding. It may be from the discomfort of chronic indigestion due to improper food. In bottle-fed infants it is often the result of overfeeding; in those who are nursed it is often due to hunger. A common cause is frequent night feeding; an infant who is fed three or four times during the night is almost invariably a bad sleeper.

2. Disturbed sleep or sleeplessness may be due to causes purely nervous. Such are bad habits acquired by faulty training; as when the nursery is lighted and the child taken from its crib whenever it wakes or cries; or when some of the contrivances for inducing sleep have been used. Any excitement or romping play just before bedtime, and fears aroused by pictures or stories, are frequent causes. Children who inherit from their parents a nervous

---

constitution are more likely to suffer from sleep disturbances than are others.

3. There may be physical discomfort from cold feet, insufficient or too much clothing, want of fresh air in the sleeping room, or interference with easy breathing due to obstruction from large tonsils or adenoids.

4. Chronic pains or frequently recurring night pains may be causes of disordered sleep, when a child wakes with a sudden sharp cry. In infants this is most often due to scurvy, sometimes to syphilis. In older children it may be the earliest symptom of disease of the hip or spine.

5. Sleeplessness and disturbed sleep are frequent whenever the general condition falls much below a healthy standard. Thus they are seen in infants who are not thriving and in children suffering from marked anæmia.

*How are children who sleep too little, or whose sleep is constantly disturbed, to be treated?*

Never by the use of soothing sirups or other medicines. Successful treatment consists in the discovery and removal of the cause of the disturbance.

*Do children ever sleep too much?*

It is doubtful if healthy children ever do. Ex-

cessive sleep is an important symptom of some diseases of the brain. Otherwise it seldom if ever occurs unless soothing sirups or other drugs have been given.

#### EXERCISE

*Is exercise important for infants?*

It is as necessary for them as for older children.

*How is it obtained?*

A young baby gets its exercise by screaming, waving its arms, kicking, etc. The clothing should not be so tight as to make these movements impossible. At least twice a day the infant should be allowed for fifteen or twenty minutes the free use of its limbs by permitting it to lie upon a bed in a warm room, with all clothing except the shirt, stockings, and napkin removed. Later, when in short clothes, the baby may be put upon a thick blanket or quilt laid upon the floor, and be allowed to tumble about at will. A nursery fence two feet high, made to surround a mattress, is an excellent device and makes a convenient box stall for the young animal, where it can learn to use both its arms and legs without the danger of injury. Only by exercise such as this do the muscles have an opportunity to develop properly.

## THE CRY

*When is crying useful?*

In the newly born infant the cry expands the lungs, and it is necessary that it should be repeated for a few minutes every day in order to keep them well expanded.

*How much crying is normal for a very young baby?*

From fifteen to thirty minutes a day is not too much.

*What is the nature of this cry?*

It is loud and strong. Infants get red in the face with it; in fact, it is a scream. This is necessary for health. It is the baby's exercise.

*When is a cry abnormal?*

When it is too long or too frequent. The abnormal cry is rarely strong, often it is a moaning or a worrying cry, sometimes only a feeble whine.

*What are the causes of such crying?*

Pain, temper, hunger, illness, and habit.

*What is the cry of pain?*

It is usually strong and sharp, but not generally continuous. It is accompanied by contraction of the

features, drawing up of the legs, and other symptoms of distress.

*What is the cry of hunger?*

It is usually a continuous, fretful cry, rarely strong and lusty.

*What is the cry of temper?*

It is loud and strong and accompanied by kicking or stiffening of the body, and is usually violent.

*What is the cry of illness?*

There is usually more of fretfulness and moaning than real crying, although crying is excited by very slight causes.

*What is the cry of indulgence or from habit?*

This is often heard even in very young infants, who cry to be rocked, to be carried about, sometimes for a light in the room, for a bottle to suck, or for the continuance of any other bad habit which has been acquired.

*How can we be sure that a child is crying to be indulged?*

If it stops immediately when it gets what it wants, and cries when it is withdrawn or withheld.

*What should be done if a baby cries at night?*

One should get up and see that the child is com-

fortable—the clothing smooth under the body, the hands and feet warm, and the napkin not wet or soiled. If all these matters are properly adjusted and the child simply crying to be taken up, it should not be further interfered with. If the night cry is habitual some other cause should be sought (see page 121).

*How is an infant to be managed that cries from temper, habit, or to be indulged?*

It should simply be allowed to "cry it out." This often requires an hour, and in extreme cases, two or three hours. A second struggle will seldom last more than ten or fifteen minutes, and a third will rarely be necessary. Such discipline is not to be carried out unless one is sure as to the cause of the habitual crying.

*Is it likely that rupture will be caused from crying?*

Not in young infants if the abdominal band is properly applied, and not after a year under any circumstances.

#### LIFTING CHILDREN

*How should a young baby be lifted from its bed?*

The right hand should grasp the clothing below the feet, and the left hand should be slipped beneath

the infant's body to its head. It is then raised upon the left arm.

*What is the advantage of this?*

The entire spine is supported, and no undue pressure is made upon the chest or abdomen, as often happens if the baby is grasped around the body or under the arms.

*How should a child old enough to run about be lifted?*

Always by placing the hands under the child's arms, and never by the wrists.

*What injury may be inflicted by lifting the child by the wrists or hands?*

Often serious injury is done to the elbow or shoulder joints.

#### THE TEMPERATURE

*What is the normal temperature of an infant?*

The normal temperature varies more than in adults. In the rectum it usually fluctuates between  $98^{\circ}$  and  $99.5^{\circ}$  F.; a rectal temperature of  $97.5^{\circ}$  F. or of  $100.5^{\circ}$  F. is of no importance whatever unless it continues.

*Where should the temperature of infants and young children be taken?*

The rectum is altogether the best place, and next to this the groin. The rectal temperature is from half a degree to a degree higher than that in the groin.

*How long should the thermometer be left in place to take the temperature?*

Two minutes in the rectum, and five minutes in the groin.

*Is the temperature of a young child a good guide as to the severity of its symptoms in illness?*

As a rule it is. A temperature of 100° to 102° F. commonly means a mild illness, and one of 104° F. or over a serious one. The duration of the fever is, however, even more important than the height of the temperature. It should be remembered that in all young children slight causes often produce a high temperature which lasts for a few hours; one should not therefore be unduly alarmed unless the temperature continues high, or is accompanied by other important signs of illness.

*Is not a high temperature a more serious symptom in a young child than in an adult?*

The opposite is rather the case. Young children are extremely sensitive to conditions which produce fever, and the thermometer often gives an exaggerated idea of the severity of the symptoms. A cause

which in an adult might produce a temperature of 102° F. or 103° F., in a young child would very likely be accompanied by a temperature of 104° or 105° F.

#### NERVOUSNESS

*What are the principal causes of excessive nervousness in infants and young children, and what can be done to prevent this?*

The most important cause is the delicate structure of the brain at this time, and its rapid growth. It grows as much during the first year as during all the rest of life. This requires quiet and peaceful surroundings. Infants who are naturally nervous should be left much alone, should see but few people, should be played with very little, and should never be quieted with soothing sirups or the "pacifier."

*At what age may playing with babies be begun?*

Babies under six months old should never be played with; and the less of it at any time the better for the infant.

*What harm is done by playing with very young babies?*

They are made nervous and irritable, sleep badly, and suffer from indigestion and in many other respects.

---

*When may young children be played with?*

If at all, in the morning, or after the midday nap; but never just before bedtime.

#### TOYS

*What points should guide one in selecting toys and playthings for an infant?*

The instinct in a baby to put everything into the mouth is so strong that nothing should be given that cannot be safely treated in this way. Hence one should choose things which are smooth, those which can be easily washed, and those which cannot be swallowed.

One should avoid (1) toys with sharp points or corners; (2) those with loose parts that might be detached or broken off and swallowed; (3) small objects which might be swallowed or pushed into the nose or ear, such as coins, marbles, and safety-pins, also beads and buttons unless strung upon a stout cord; (4) painted toys; (5) those covered with hair or wool. Infants have often been severely injured by swallowing what they have pulled off from their small toy animals.

*What points are to be considered in selecting the toys and playthings of a child over two years old?*

It should be remembered that toys are not mere-

ly a source of amusement, but that they have an educational value as well. Those are therefore to be preferred the use of which develops the child's imagination, and with which he can be taught to amuse himself. For boys nothing can surpass blocks, toy soldiers, balls, engines, and cars; and for girls, dolls and housekeeping sets. The complicated mechanical toys now so much in vogue give only a momentary pleasure, and as soon as the wonder at their operation has worn off, they have lost interest for the child except that which he gets in breaking them to see how the thing worked.

*What important things can be taught children with their toys and how may this be done?*

The imagination may be developed, and children may be trained to habits of neatness, order and regularity, and to concentration of mind.

To this end toys should be kept in an orderly way upon a shelf in the nursery or in a closet, never piled in a miscellaneous heap in the corner of the room. Children should select their toys and play with one thing at a time, which they should be taught to put away in its place before another is given. They should never be allowed to have a dozen things strewn about the room at one time, with none of which they are occupied.

## KISSING

*Are there any valid objections to kissing infants?*

There are many serious objections. Tuberculosis, diphtheria, and many other grave diseases may be communicated in this way. The kissing of infants upon the mouth by other children, by nurses, or by people generally, should under no circumstances be permitted. Infants should be kissed, if at all, upon the cheek or forehead, but the less even of this the better.

## CONVULSIONS

*What should be done for a child in convulsions before a doctor arrives?*

Keep the child perfectly quiet with ice at the head, put the feet in a mustard bath, and roll the entire body in large towels which have been dipped in mustard water (two heaping tablespoonfuls of mustard to one quart of tepid water), and have plenty of hot water and a bath tub at hand, so that the doctor can give a hot bath if he thinks it advisable.

*When is a hot bath useful?*

If the convulsions have continued until the pulse is weak, the face very pale, the nails and lips blue,

and the feet and hands cold, the hot bath will be useful by bringing blood to the surface and relieving the heart, lungs, and brain.

*How should the bath be given?*

The temperature should not be over 106° F.; this should always be tested by a thermometer if one can be obtained. Without this precaution, in the excitement of the moment, infants have frequently been put into baths so hot that serious and even fatal burns have been produced. If no thermometer is available the nurse may plunge her arm to the elbow into the water. It should feel warm, but not so hot as to be at all uncomfortable. One half a teacupful of powdered mustard added to the bath often adds to its efficacy.

#### FOREIGN BODIES

*What should be done if a foreign body has been swallowed?*

First, examine the throat with the finger to see if it has lodged there, and if so remove it. If it has passed from the throat it has usually gone into the stomach.

*What should be done in this case?*

Give the child plenty of dry food, like bread, potato, etc., but under no circumstances either an

---

emetic or cathartic. An infant may have its usual food.

*What harm would a cathartic do?*

It is likely to hurry the foreign body too rapidly through the intestine and in this way do harm; otherwise it becomes coated with faecal matter and passes the intestine usually without doing injury.

*What should be done if a child gets a foreign body into the ear?*

Unless this can easily be removed with the fingers it should not be meddled with, for it is likely to be pushed farther into the ear. The child should be taken to a physician.

*What should be done if there is a foreign body in the nose?*

The child should blow his nose strongly while the empty nostril is compressed. Unless this removes it a physician should be called. Meddlesome interference is always harmful.

*What are the symptoms of colic?*

There is a strong, hard cry, which comes suddenly and returns every few minutes. With this

there is drawing up of the feet, contraction of the muscles of the face, and other signs of pain. The abdomen is usually tense and hard.

*What should be done for a baby with colic?*

First, see that the feet are warm. Place them against a hot-water bag, or hold them before an open fire; apply a hot flannel to the abdomen, or let the child lie upon its stomach across a hot-water bag. If the colic continues, a half teacupful of warm water containing ten drops of turpentine may be injected into the bowels with a syringe; at the same time the abdomen should be gently rubbed so as to start the wind. If the gas is in the stomach, half of a soda mint tablet may be given in a tablespoonful of very warm water.

#### EARACHE

*What are the symptoms of earache?*

The pain is generally severe and accompanied by a sharp scream; the child often puts the hand to the affected ear, or cries whenever it is touched. The pain is likely to be prolonged and continuous.

*How should a child with earache be treated?*

The ear should be irrigated with a solution of boric acid (twenty grains to the ounce) as warm as can be borne. Dry heat may then be applied in sev-

---

eral ways. The ear having been first covered with cotton, a small hot-water bag or one filled with hot salt or bran, may be bound over it with a bandage; or a small butter plate heated in hot water may be used in the same way. The hot-water bag may be held against the ear or the child may lie with his head upon it. The use of such substances as oil and laudanum in the ear is not to be recommended.

#### CROUP

*What are the symptoms of croup?*

There is a hollow, dry, barking cough, with some difficulty in breathing.

*When is this likely to come on?*

Usually at night.

*Is simple croup dangerous?*

The ordinary croup of infants is spasmodic croup, and is very rarely dangerous, although the symptoms seem very alarming.

*What are the symptoms?*

In a mild attack there is simply noisy breathing, especially on drawing in the breath, with a tight, barking, or croupy cough. In a severe attack the child's breathing is more noisy and becomes difficult.

*What is the dangerous form of croup?*

Membranous croup, which is the same thing as diphtheria of the larynx.

*How does this develop?*

Gradually; very rarely does it come on suddenly.

*What should be done for a baby who has spasmodic croup?*

The room should be very warm, hot cloths or poultices should be applied over the throat, and either a croup kettle or an ordinary tea-kettle kept boiling in the room. This is more efficacious if the child is placed in a tent made by a raised umbrella with a sheet thrown over it, and the steam introduced beneath the tent. If the symptoms are urgent, ten drops of the sirup of ipecac should be given every fifteen minutes until free vomiting occurs. Whenever the symptoms reach a point where breathing becomes difficult, a doctor should be summoned without delay.

#### CONTAGIOUS DISEASES

*What are the first symptoms of measles?*

Measles comes on rather gradually with cough, sneezing, watery eyes and nose, much like an ordinary cold in the head. The eruption appears after

---

three or four days, first upon the face and neck as small red spots, and spreads slowly over the body.

*Is measles a serious disease?*

In infants and during the winter season it is likely to be very serious on account of the danger of bronchitis and pneumonia, which frequently accompany it. In children over four years old it is generally not severe. No child should be voluntarily exposed to this disease, and particularly one who is delicate or prone to disease of the lungs should be protected against it.

*When and how is measles contagious?*

Measles may readily be conveyed in the early stage and from the very beginning of the catarrhal symptoms, two or three days before any eruption is present. It is much less contagious after the eruption fades. Measles is not often carried by healthy persons. Its poison does not cling long to a sick room.

*What is German measles?*

German measles, or rubella, is a distinct contagious disease and has nothing to do with ordinary measles. It is not serious, and it is extremely rare for a child to be very sick with it. There is usually a very extensive eruption which may cover the body, but there are very few other symptoms.

*What are the first symptoms of scarlet fever?*

Generally it comes suddenly, with vomiting, high fever, and sore throat. The eruption usually appears within twenty-four hours as a red blush, first upon the neck and chest, and spreads rapidly over the body.

*When and how is scarlet fever contagious?*

Scarlet fever is only slightly contagious for the first one or two days of the attack. It is most contagious during the height of the disease and during desquamation. It is often carried by healthy persons and by the clothing or bedding of one sick with it. Its poison clings long to the sick-room.

*How does whooping-cough begin?*

For a week or ten days it cannot be distinguished from an ordinary cold on the chest. Then the attacks of coughing gradually become harder and last longer, the child gets very red in the face and sometimes vomits its food. After a severe coughing fit it catches its breath with a peculiar noise known as the "whoop."

*How does chicken-pox begin?*

It usually comes out gradually, as widely scattered pimples over the scalp, face, and body, many of which soon become small vesicles, resembling tiny

---

blisters. There is itching and some local discomfort but very little fever, and the child rarely seems to be very ill.

*How does diphtheria begin?*

Sometimes suddenly, but usually very gradually, with sore throat and often swelling of the glands of the neck, with white patches upon the tonsils, or a very free discharge, which may be bloody, from the nostrils.

*How long after exposure do the first symptoms appear in the different diseases?*

In scarlet fever in from three to five days, rarely later than a week; in measles in from nine to fourteen days, occasionally as late as twenty days; in whooping-cough in from one to two weeks; in chicken-pox in from fourteen to sixteen days; in German measles in from ten to sixteen days. In diphtheria it varies much; it may be only one day, and it may be one or two weeks.

*Which of these diseases are most contagious?*

Measles and chicken-pox are very contagious, and very few children who have not had them can come near a person suffering from either disease without taking it. Whooping-cough is almost as contagious as measles, and for young babies even more

so. A very close exposure is not necessary in the case of either of these diseases, and whooping-cough can undoubtedly be contracted in the open air. Scarlet fever and diphtheria are much less contagious; for both of these a pretty close exposure is necessary, and even then many who are exposed escape.

*How long should a child with any of these diseases be kept away from other children?*

With measles, two weeks after the rash has gone; with scarlet fever, at least four weeks after the rash has gone, and longer if the peeling is not over or if the ears are running; with whooping-cough, for two months, or so long as the paroxysmal cough continues; with chicken-pox, until all crusts have fallen off, or about three weeks after the eruption appears; with German measles for one week after the eruption has faded; with diphtheria at least ten days after the throat is well in a very mild case, and four weeks if the case has been severe.

*What should be done when a child shows the first symptoms of serious illness?*

The child should be put to bed. If it is an infant, the food should be diluted to one half the usual strength; if an older child, only fluid food should be given. If the child seems feverish, take the temperature. If the bowels are constipated, give a tea-

---

spoonful of castor oil, but no other medicine without the doctor's orders. Send for the doctor at once, and until he comes carefully exclude all other children from the room.

*By what nursery training may the examination and treatment of sick children be made much easier?*

By teaching all children to gargle, to show the throat, to take pills, and by constantly teaching them to regard the doctor as the child's best friend, and his visits as a great treat. On no account should a child be frightened into obedience by threats of what the doctor will do.

With care and patience most children may be taught to gargle and take pills at four or five years, and to show the throat willingly at two or three. All these matters should be made a part of the child's education.

#### SCURVY

*What is scurvy and how is it produced?*

Scurvy is a disease of general nutrition, usually caused by the long-continued use of improper food. Most of the cases come from the use of the prepared infant's foods sold in the stores, especially when they are given without fresh milk; occasionally the use of condensed milk and of sterilized milk is followed by scurvy; sometimes it is seen when, owing to feeble

digestion, it has been necessary to make cow's milk very weak for a long time.

*What symptoms are seen in an infant with scurvy?*

At first there is only indefinite and occasional soreness in the legs so that the child cries out when handled. As this soreness becomes more severe the child is often thought to have rheumatism. The gums swell and are of a deep purple colour. There may be bleeding from the gums, nose, bowels, or black-and-blue spots may be seen upon the legs. The ankles and knees may swell. The child grows very pale, loses appetite and weight, and sleeps badly.

*What should be done when an infant shows signs of scurvy?*

The diet should at once be changed to fresh milk, properly modified according to the child's digestion, but not sterilized or pasteurized. The juice of a sweet orange should be given, best about an hour before the feeding. At first one or two teaspoonfuls, four or five times a day; later, more may be given if the symptoms are not improved.

Properly treated an infant with scurvy generally recovers promptly and completely. If not recognised, or untreated, it may cause death.

## CONSTIPATION

*When it is necessary to move the bowels immediately, what are some of the easiest methods?*

An injection of one tablespoonful of sweet oil may be given, or half a teaspoonful of glycerine in one tablespoonful of water, or a teacupful of tepid soap and water, or a glycerine suppository. None of these should be continued excepting under the physician's directions.

*What sort of a syringe is to be preferred for giving an injection to an infant?*

The bulb syringe is the simplest; this consists of an oval bulb of soft rubber and a soft rubber or a hard rubber tip. It holds one or two ounces.

*What is the most essential thing in preventing or overcoming constipation?*

The formation of the habit of having the bowels move every day regularly at the same hour, and proper early training (see page 117).

*What is the best hour?*

In most cases immediately after the first meal in the morning.

*What are some simple means by which constipation may be relieved?*

The best are diet, suppositories, and massage.

The changes to be made in the milk of constipated infants have been mentioned on page 77. The addition to the milk of some of the malted foods, such as Mellin's food or malted milk, is sometimes useful. For little children the fruit juices are particularly beneficial when given half an hour or more before the first morning feeding, with half a glass of water.

For older children the amount of white bread, toast, and potato, should be reduced, and green vegetables, oatmeal, and Graham bread given, with plenty of fruit twice a day. Raw scraped apples are sometimes of more value than any other fruit.

The best suppositories for continuous use are probably the gluten suppositories of the Health Food Company. One should be given the first thing in the morning. They act rather slowly, usually in about two hours. In obstinate cases one may also be used at bedtime. Glycerine suppositories act more quickly, but are too irritating for regular use.

Massage consists in rubbing the abdomen, which may be done in one of two ways: Beginning at the right groin, the hand is carried up to the ribs, then across to the opposite side, then around to the left groin. The abdomen is stroked gently at first, and afterward deeper pressure used as the child becomes

accustomed to it. The second method is by rubbing the deeper parts with a circular movement—the fingers not moving upon the skin—making a series of small circles, beginning at the right groin and following the same course as described above. Either method should be employed for six or eight minutes twice a day, at almost any regular time, except soon after a meal.

#### DIARRHŒA

*In case a child is taken with diarrhœa, what should be done?*

With a moderate looseness of the bowels in an older child, solid food should be stopped, and boiled milk given diluted with gruel; the child should be kept perfectly quiet, as walking about always aggravates such a disturbance. If the symptoms are more severe and attended by fever and vomiting, all milk should be stopped at once, and only broth, barley water, or some thin gruel given. Some cathartic, usually castor oil, is required with a severe attack.

If the patient is an infant, the milk should be diluted and especially should the fat be reduced (see page 78). In severe attacks with vomiting or frequent foul stools, all food should be stopped for at least twelve hours and all milk for a longer time, and the bowels freely moved by a cathartic.

*Why is a cathartic necessary if the movements are already frequent?*

Such movements are nearly always due to an irritation in the bowel, set up by the fermenting food which has not been digested. The diarrhoea is Nature's effort to get rid of the irritant. Nothing to stop the movements should be given until the bowels have been thoroughly cleared by the treatment mentioned.

#### BAD HABITS

*What are the most common bad habits of young children?*

Sucking, nail-biting, dirt-eating, bed-wetting, and masturbation.

*What do children suck?*

Most frequently the thumbs or fingers, sometimes the clothing or blanket often the "pacifier" or rubber nipple.

*When is this habit most frequently seen?*

It begins in quite early infancy, and if not broken may last until children are six or seven years old.

*Is the sucking habit a harmful one?*

When persisted in it may produce a misshapen mouth or fingers. It constantly stimulates the flow

---

of saliva and certainly aggravates disturbances of digestion during which the sucking habit is likely to be practised. It may lead to thrush or other forms of infection of the mouth. It is not necessary as a means of quieting a child, though it may in some degree cover up the consequences of bad feeding or bad training. On no account should the habit of sucking the "pacifier" be allowed as a means of putting children to sleep, or of quieting them while restless from dentition or indigestion.

*How is the sucking habit to be controlled?*

One should be sure in the first place that the constant sucking of fingers is not due to hunger from insufficient food. Sucking of the hands may often be controlled by wearing mittens or fastening the hands to the sides during sleep. In more obstinate cases it may be necessary to confine the elbow by small pasteboard splints to prevent the child from bending the arm so as to get the hand to the mouth.

*When are nail-biting and dirt-eating seen, and how are they to be controlled?*

These habits belong especially to children over three years old. They are seen particularly in those who are excessively nervous or whose general health is below par; sometimes in those who develop serious nervous diseases later in life. Children with such

tendencies should be closely watched, and every means used to break up these habits early. Dirt-eating is a morbid craving which is rarely seen in a normal child.

*At what age may a child generally be expected to go without wetting the bed during the night?*

Usually at two and a half years, if it is taken up late in the evening. Some children acquire control of the bladder at night when two years old, and a few not until three years. After three years habitual bed-wetting is abnormal.

*How should a young child addicted to bed-wetting be managed?*

At three or four years of age, punishments are sometimes useful, especially when it seems to depend more upon the child's indifference than anything else. They are of no value in older children, rewards being much more efficacious. In all cases one should give a child plenty of milk and water early in the day, but no fluids after 4 p. m., the supper being always of solid or semi-solid food. The child should be taken up regularly at ten o'clock or thereabouts. It often happens that the formation or continuance of the habit is due to the child being in poor general condition, to some irritation in the urine, or in the genital organs. Unless the simple

means mentioned are successful the child should be placed under the charge of a physician.

*What is masturbation?*

It is the habit of rubbing the genital organs with the hands, with the clothing, against the bed, or rubbing the thighs together. Sometimes the child sits upon the floor, crosses its thighs tightly and rocks backward and forward. Many of these things are passed over lightly and are regarded for months as simply a "queer trick" of the child. It may be seen at any age, even in those not more than a year old, and in both sexes.

*How should such a child be treated?*

Masturbation is the most injurious of all the bad habits, and should be broken up just as early as possible. Children should especially be watched at the time of going to sleep and on first waking. Punishments are of little avail, and usually make matters worse. Some local cause of irritation is often present, which can be removed. Medical advice should at once be sought.

## THE TEETH IN HEALTH AND DECAY.

---

### The Care of the Teeth.

By S. A. HOPKINS, M.D., D.D.S., Professor of Theory and Practise of Dentistry in Tufts College Dental School, Boston, Mass. Illustrated. 12mo. Cloth, 75 cents net; postage, 7 cents additional.

The author points out in a concise manner how decay of the teeth may be prevented and dental operations reduced to a minimum. The dentist will find much that will be useful in his practise, and just the suggestions to make to his patients when urging upon them the importance of proper care of the teeth. No physician can read it without an awakening sense of the important bearing diseased teeth have upon the general health; nor can he fail to gain many practical ideas that will be of immense value in his practise. To mothers of growing children the book will be most valuable, for until this book was written no practical guide existed, especially in a form adapted to the needs of the household. The author points out very clearly what can be done to improve the teeth, and gives practical directions for the guidance of those entrusted with the care of children. It is also shown how the teeth of adults may be preserved, and how many dental operations may be avoided. The book is interestingly written in plain language.

#### TABLE OF CONTENTS.

CHAPTER I. History of Dentistry—Uses of Teeth. II. Cause of Decay. III. Predisposing Causes—Lack of Exercise. IV. Food. V. Food (continued). VI. Eating Slowly. VII. Irregularities. VIII. Other Mouth Disturbances. IX. Prevention of Caries or Decay. X. Brushing, Mouth-Washes, etc. XI. Toothache and the Teeth of the Poor. XII. Anatomy.

# AN OUTDOOR BOOK FOR WOMEN.

---

## The Woman's Book of Sports.

*A Practical Guide to Physical Development and Outdoor Recreation.* By J. PARMLY PARET. 12mo. With many Illustrations. Cloth, \$1.00 net; postage, 8 cents additional.

This is a practical guide by a practical writer for the amateur sportswoman. Golf, lawn-tennis, sailing, swimming, bicycling, and basket-ball have each their chapters, and the devotee of any of these sports will find here much that will be instructive. The book is an invaluable guide for the feminine novice in sports, for each game is treated from the elementary standpoint, the first rudiments of skill in all being explained in a simple and direct manner for practical use. Here will be found the condensed teachings of the best professional instructors, and any woman should quickly learn any of the games by studying its chapters.

A unique feature of this book is the chapter on men's sports from a woman's point of view—from the view-point of the spectator. Football, baseball, yacht racing, rowing, and athletics are all fully explained, so that the uninitiated spectator, either man or woman, may learn enough of any of these sports in a half-hour's reading of its chapters to appreciate the game to be seen. The yachting chapter has been specially prepared with an eye to the coming international races for the America's Cup.

It is thoroughly illustrated with half-tone reproductions (all full-page size, with large figures) of instantaneous photographs showing the correct and incorrect methods in the different sports. In illustrating the drive in golf, for instance, three illustrations show the beginning, the middle, and the end of the swing as it should be made, while a fourth shows the incorrect finish of the swing, without the all-important "carry through." Other sports are treated in the same way.

# SICKNESS, HYGIENE, AND HEALTH.

---

## In Sickness and in Health.

A Manual of Domestic Medicine and Surgery, Hygiene, Dietetics, and Nursing, dealing in a practical way with the problems relating to the maintenance of health, the prevention and treatment of disease, and the most effective aid in emergencies. Edited by J. WEST ROOSEVELT, M.D., late Physician in Charge of Seton Hospital for Consumptives; Visiting Physician to Bellevue Hospital; and Attending Physician to Roosevelt Hospital, New York. Complete in one volume of over 1,000 pages. Illustrated with 4 Colored Plates and numerous Engravings. Full Analytical Index. 8vo. Handsome cloth binding, \$5.00.

## Health Primers.

Edited by J. LANGDON DOWN, M.D., F.R.C.P.; HENRY POWER, M.B., F.R.C.S.; J. MORTIMER-GRANVILLE, M.D.; JOHN TWEEDY, F.R.C.S. In square 16mo volumes. Cloth, 40 cents each.

- I. EXERCISE AND TRAINING.
- II. ALCOHOL: Its Use and Abuse.
- III. PREMATURE DEATH: Its Promotion or Prevention.
- IV. THE HOUSE AND ITS SURROUNDINGS.
- V. PERSONAL APPEARANCE IN HEALTH AND DISEASE.
- VI. BATHS AND BATHING.
- VII. THE SKIN AND ITS TROUBLES.
- VIII. THE HEART AND ITS FUNCTIONS.
- IX. THE NERVOUS SYSTEM.

Though it is of the greatest importance that books upon health should be in the highest degree trustworthy, it is notorious that most of the cheap and popular kind are mere crude compilations by incompetent persons, and are often misleading and injurious. Impressed by these considerations, several eminent medical and scientific men of London combined to prepare a series of **HEALTH PRIMERS** of a character that should be entitled to the fullest confidence.

"HEARTILY RECOMMENDED TO ALL WHO HAVE TO  
CARE FOR THE SICK."—*Newark (N. J.) News.*

---

## A Text-Book of Nursing.

For the use of Training Schools, Families, and Private Students. Compiled by CLARA S. WEEKS-SHAW. Third Edition, revised and enlarged. With many Illustrations. 12mo. Cloth, \$1.75.

This book, first introduced to the public by Prof. Edward L. Youmans, to whose most kind encouragement and assistance it owed its existence, is now for the second time revised and brought up to date under the supervision of his niece, Dr. Alice C. Youmans. It follows the same practical lines as the earlier editions and, until something more comprehensive is offered, it is hoped will continue to be of use to nurses both amateur and professional.

### ITS HIGH STANDING.

"A valuable book."—*New York American.*

"It covers the whole subject."—*Philadelphia Press.*

"Well written, practical, and authoritative."—*Detroit Free Press.*

"It has the recommendations of the highest medical authorities."  
—*Chicago Tribune.*

"Has long been known among nurses as the most reliable and comprehensive work of its kind."—*New York Commercial Advertiser.*

---

## A VOLUME FOR EMERGENCIES.

---

### A Manual of Instruction in the Principles of Prompt Aid to the Injured.

Designed for Military and Civil Use. By ALVAH H. DOTY, M.D., Major and Surgeon, Ninth Regiment, N. G., N. Y., Attending Surgeon to Bellevue Hospital Medical Dispensary, New York. Fourth edition, revised to date. With 96 Illustrations. 12mo. Cloth, \$1.50 net.

This book is intended to impart the knowledge necessary for the prompt and intelligent care of persons suffering from hemorrhage, fractures, dislocations, wounds, contusions, burns, shock, sprains, poisoning, the effects of heat or cold, apoplexy, epilepsy, etc. It explains the proper treatment of those rescued from drowning, and other accidents which are liable to occur at any time, the results of which may be materially influenced by the care and attention which the sufferer receives at the outset. Each topic is explained in plain and simple language, and when medical terms are used their lay synonyms are also given. Of special interest to military organizations is the manner in which the matter has been arranged and points introduced that will be of use to the ambulance corps. The United States Army Drill Regulations for the Hospital Corps are given in complete form with profuse illustrations. In the new edition the chapter on disinfection has been entirely rewritten, in order to embody the results obtained by the latest scientific investigation. Those relating to wounds, hemorrhage, hygiene, poisons, etc., have been thoroughly revised. It is a work that should be in every home and office, and in the Company rooms of every military organization.

D. APPLETON AND COMPANY, NEW YORK.

---

---

“A handbook of immediate practical value.”

—*The Pioneer Press (St. Paul).*

---

## How to Know Oriental Rugs.

By MARY BEACH LANGTON. Containing 20 full-page illustrations, 12 of which are in colors. 12mo. Cloth, \$2.00 net; postage, 15 cents additional.

“This attractive new volume from the pen of a St. Paul woman is entitled to something more than the average recognition a work of the kind in its mission of mere timeliness is accorded. Written upon a subject of wide and steadily increasing popularity, not as yet overburdened with special literature, it not only fills a distinct and long-felt want, but in the strong, clear, and all-round eminently satisfactory manner in which the entire field is covered it becomes at once a handbook of immediate practical value. The aim of the author in preparing the volume has been simply to teach the general public how to know Oriental rugs, to help them to understand their value and their suitability, and to make it possible for them to buy intelligently and with some satisfaction to themselves. The book describes the meaning of the various styles and helps the reader to appreciate wherein the chief beauties lie, being arranged throughout with a view to general requirements. For purposes of reference an index is provided, but the book can be read from the first page to the last with the strongest interest and profit.”—*The Pioneer Press (St. Paul).*

“The rugs selected for illustration are excellent examples of the types here represented, and the color work is admirable. Mrs. Langton’s classifications are more satisfactory than those employed by previous writers on the same subject. The cleverness and superiority of classification are heightened by the fact that at the beginning of each chapter are grouped the names of the rugs included under the general heading.”—*The Upholsterer (New York).*

## THE ARTISTIC CRAFTS SERIES.

Edited by W. R. LETHABY.

There is a broad purpose in this series of handbooks on the Artistic Crafts. It is the intention to provide trustworthy textbooks of work-shop practice from the point of view of experts who have accurately examined the methods current in the shops, who are prepared to say of what good workmanship consists, and to establish a standard of equality in the crafts, more especially associated with design. Workmanship where separated by too wide a gulf from fresh thought—that is, from design—eventually decays, and, on the other hand, ornamentation apart from workmanship is apt to be unreal and affected. Furthermore, there is a demand for such standard works from those who put artistic craftsmanship before people as furnishing reasonable occupation for those who would gain a livelihood, with a chance of reaching a distinct measure of success.

ILLUSTRATED. 12mo. Half-Bound.

---

### **Bookbinding, and the Care of Books.**

A Handbook for Amateurs, Bookbinders, and Librarians. By DOUGLAS COCKERELL. With Drawings by Noel Rooke, and other Illustrations. \$1.25 net.

## NOTABLE BOOKS ON HYGIENE AND NURSING.

---

### Hygiene for Girls.

By IRENÆUS P. DAVIS, M.D. 16mo. Cloth, \$1.25.

Many a woman whose childhood was bright with promise endures an after-life of misery because, through a false delicacy, she had been permitted to grow up in ignorance of her physical nature and requirements, while in most other subjects she might have been well informed. Not only is it desirable that girls should at the proper time understand themselves and thus become acquainted with the more important offices for which they were created, but it is absolutely essential to pure health. Dr. Davis, an eminent man in his sphere of work, has given us in this treatise a clear and delicate interpretation of the habits and associations, the amusements and hygienic practices, that are the strong points to a pure and useful existence.

### The Physiology of Bodily Exercise.

By FERNAND LAGRANGE, M.D. 12mo. Cloth, \$1.75.

CONTENTS.—Part I. Muscular Work. II. Fatigue. III. Habituation to Work. IV. The Different Exercises. V. The Results of Exercise. VI. The Office of the Brain in Exercise.

### Notes on Nursing: What it is, and what it is not.

By FLORENCE NIGHTINGALE. 12mo. Cloth, 75 cents.

“Every woman, or at least almost every woman, has at one time or another of her life charge of the personal health of somebody, whether child or invalid; in other words, every woman is a nurse. How immense and how valuable, then, would be the product of her united experience if every woman would think how to nurse! I do not pretend to teach her how; I ask her to teach herself, and for this purpose I venture to give her some hints.”

## BOOKS FOR THE HOUSE.

---

### The Chemistry of Common Life.

By the late Prof. JAMES F. W. JOHNSTON. A New Edition, revised and enlarged, and brought down to the present time, by Arthur Herbert Church, M.A., Oxon., Author of "Food: Its Sources, Constituents, and Uses." Illustrated with Maps and numerous Engravings on Wood. 12mo. Cloth, \$2.00.

SUMMARY OF CONTENTS.—The Air we Breathe; the Water we Drink; the Soil we Cultivate; the Plant we Rear; the Bread we Eat; the Beef we Cook; the Beverages we Infuse; the Sweets we Extract; the Liquors we Ferment; the Narcotics we Indulge in; the Poisons we Select; the Odors we Enjoy; the Smells we Dislike; the Colors we Admire; What we Breathe and Breathe for; What, How, and Why we Digest; the Body we Cherish; the Circulation of Matter.

### Handbook of Household Science.

A Popular Account of Heat, Light, Air, Aliment, and Cleansing, in their Scientific Principles and Domestic Applications. With numerous Illustrative Diagrams. By EDWARD L. YOUNMANS, M.D., Author of "The New Class Book of Chemistry"; Editor of "The Correlation and Conservation of Forces," "The Culture Demanded by Modern Life," etc. 12mo. Cloth, \$1.75.

The purpose of the author has been to condense within the limits of a convenient manual the largest possible amount of interesting and valuable scientific information of those agents, materials, and operations in which we have a concern, chiefly as dwellers in houses. He has presented the subject in such a manner as to make reading and study both agreeable and instructive.

### Social Etiquette in New York.

Rewritten and enlarged. Cloth, gilt, \$1.00.

Special pains have been taken to make this work represent accurately existing customs in New York society. The subjects treated are of visiting and visiting cards, giving and attending balls, receptions, dinners, etc., débuts, chaperons, weddings, opera and theater parties, costumes and customs, addresses and signatures, funeral customs, covering so far as practicable all social usages.
